Again, the push! operation is destructive so the stack is changed:

   a
      [9,2,3,4,5]

Another name for push! is insert!, which treats the stack as a BagAggregate:

   insert!(8,a)
      [8,9,3,4,5]

and it modifies the stack:

   a
      [8,9,3,4,5]

The inspect function returns the top of the stack without modification,
viewed as a BagAggregate:

   inspect a
      8

The empty? operation returns true only if there are no element on the
stack, otherwise it returns false:

   empty? a
      false

The top operation returns the top of stack without modification, viewed
as a Stack:
```

```
   top a
      8
```

The depth operation returns the number of elements on the stack:

```
   depth a
      5
```

which is the same as the # (length) operation:

```
   #a
       5
```

The less? predicate will compare the stack length to an integer:

```
   less?(a,9)
        true
```

The more? predicate will compare the stack length to an integer:

```
   more?(a,9)
        false
```

The size? operation will compare the stack length to an integer:

```
   size?(a,#a)
        true
```

and since the last computation must alwasy be true we try:

```
   size?(a,9)
        false
```

The parts function will return the stack as a list of its elements:

```
   parts a
        [8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a stack.
Notice that the elements are pushed in reverse order:

```
   bag([1,2,3,4,5])$Stack(INT)
        [5,4,3,2,1]
```

The empty function will construct an empty stack of a given type:

```
   b:=empty()$(Stack INT)
        []
```

```
and the empty? predicate allows us to find out if a stack is empty:

   empty? b
        true

The sample function returns a sample, empty stack:

   sample()$Stack(INT)
        []

We can copy a stack and it does not share storage so subsequent
modifications of the original stack will not affect the copy:

   c:=copy a
        [8,9,3,4,5]

The eq? function is only true if the lists are the same reference,
so even though c is a copy of a, they are not the same:

   eq?(a,c)
        false

However, a clearly shares a reference with itself:

   eq?(a,a)
        true

But we can compare a and c for equality:

   (a=c)@Boolean
        true

and clearly a is equal to itself:

   (a=a)@Boolean
        true

and since a and c are equal, they are clearly NOT not-equal:

   a~=c
        false

We can use the any? function to see if a predicate is true for any element:

   any?(x+->(x=4),a)
        true

or false for every element:

   any?(x+->(x=11),a)
```

```
        false
```

We can use the every? function to check every element satisfies a predicate:

```
   every?(x+->(x=11),a)
        false
```

We can count the elements that are equal to an argument of this type:

```
   count(4,a)
        1
```

or we can count against a boolean function:

```
   count(x+->(x>2),a)
        5
```

You can also map a function over every element, returning a new stack:

```
   map(x+->x+10,a)
        [18,19,13,14,15]
```

Notice that the orignal stack is unchanged:

```
   a
        [8,9,3,4,5]
```

You can use map! to map a function over every element and change
the original stack since map! is destructive:

```
   map!(x+->x+10,a)
       [18,19,13,14,15]
```

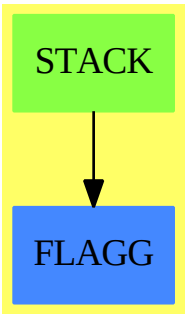
Notice that the orignal stack has been changed:

```
   a
       [18,19,13,14,15]
```

The member function can also get the element of the stack as a list:

```
   members a
       [18,19,13,14,15]
```

and using member? we can test if the stack holds a given element:



```
   member?(14,a)
       true
```

— Stream.help —

```
=====================================================================
Stream examples
=====================================================================

A Stream object is represented as a list whose last element contains
the wherewithal to create the next element, should it ever be required.

Let ints be the infinite stream of non-negative integers.
```

```
  ints := [i for i in 0..]
    [0,1,2,3,4,5,6,7,8,9,...]
                                  Type: Stream NonNegativeInteger
```

By default, ten stream elements are calculated. This number may be changed to something else by the system command

```
  )set streams calculate
```

More generally, you can construct a stream by specifying its initial value and a function which, when given an element, creates the next element.

```
  f : List INT -> List INT
                                  Type: Void

  f x == [x.1 + x.2, x.1]
                                  Type: Void

  fibs := [i.2 for i in [generate(f,[1,1])]]
    [1,1,2,3,5,8,13,21,34,55,...]
                                  Type: Stream Integer
```

You can create the stream of odd non-negative integers by either filtering them from the integers, or by evaluating an expression for each integer.

```
  [i for i in ints | odd? i]
    [1,3,5,7,9,11,13,15,17,19,...]
                                  Type: Stream NonNegativeInteger

  odds := [2*i+1 for i in ints]
    [1,3,5,7,9,11,13,15,17,19,...]
                                  Type: Stream NonNegativeInteger
```

You can accumulate the initial segments of a stream using the scan operation.

```
  scan(0,+,odds)
    [1,4,9,16,25,36,49,64,81,100,...]
                                  Type: Stream NonNegativeInteger
```

The corresponding elements of two or more streams can be combined in this way.

```
  [i*j for i in ints for j in odds]
    [0,3,10,21,36,55,78,105,136,171,...]
                                  Type: Stream NonNegativeInteger

  map(*,ints,odds)
    [0,3,10,21,36,55,78,105,136,171,...]
                                  Type: Stream NonNegativeInteger
```

Many operations similar to those applicable to lists are available for

```
streams.

  first ints
    0
                                  Type: NonNegativeInteger

  rest ints
    [1,2,3,4,5,6,7,8,9,10,...]
                                  Type: Stream NonNegativeInteger

  fibs 20
    6765
                                  Type: PositiveInteger

— domain STREAM Stream —

```
)abbrev domain STREAM Stream
++ Implementation of streams via lazy evaluation
++ Authors: Burge, Watt; updated by Clifton J. Williamson
++ Date Created: July 1986
++ Date Last Updated: 30 March 1990
++ Description:
++ A stream is an implementation of an infinite sequence using
++ a list of terms that have been computed and a function closure
```

```
++ to compute additional terms when needed.

Stream(S): Exports == Implementation where
--  problems:
--  1) dealing with functions which basically want a finite structure
--  2) 'map' doesn't deal with cycles very well

  S : Type
  B   ==> Boolean
  OUT ==> OutputForm
  I   ==> Integer
  L   ==> List
  NNI ==> NonNegativeInteger
  U   ==> UniversalSegment I

  Exports ==> LazyStreamAggregate(S) with
    shallowlyMutable
      ++ one may destructively alter a stream by assigning new
      ++ values to its entries.

    coerce: L S -> %
      ++ coerce(l) converts a list l to a stream.
      ++
      ++X m:=[1,2,3,4,5,6,7,8,9,10,11,12]
      ++X coerce(m)@Stream(Integer)
      ++X m::Stream(Integer)

    repeating: L S -> %
      ++ repeating(l) is a repeating stream whose period is the list l.
      ++
      ++X m:=repeating([-1,0,1,2,3])

    if S has SetCategory then
      repeating?: (L S,%) -> B
        ++ repeating?(l,s) returns true if a stream s is periodic
        ++ with period l, and false otherwise.
        ++
        ++X m:=[1,2,3]
        ++X n:=repeating(m)
        ++X repeating?(m,n)

    findCycle: (NNI,%) -> Record(cycle?: B, prefix: NNI, period: NNI)
      ++ findCycle(n,st) determines if st is periodic within n.
      ++
      ++X m:=[1,2,3]
      ++X n:=repeating(m)
      ++X findCycle(3,n)
      ++X findCycle(2,n)

    delay: (() -> %) -> %
```

```
    ++ delay(f) creates a stream with a lazy evaluation defined by
    ++ function f.
    ++ Caution: This function can only be called in compiled code.
  cons: (S,%) -> %
    ++ cons(a,s) returns a stream whose \spad{first} is \spad{a}
    ++ and whose \spad{rest} is s.
    ++ Note: \spad{cons(a,s) = concat(a,s)}.
    ++
    ++X m:=[1,2,3]
    ++X n:=repeating(m)
    ++X cons(4,n)

  if S has SetCategory then
    output: (I, %) -> Void
      ++ output(n,st) computes and displays the first n entries
      ++ of st.
      ++
      ++X m:=[1,2,3]
      ++X n:=repeating(m)
      ++X output(5,n)

    showAllElements: % -> OUT
      ++ showAllElements(s) creates an output form which displays all
      ++ computed elements.
      ++
      ++X m:=[1,2,3,4,5,6,7,8,9,10,11,12]
      ++X n:=m::Stream(PositiveInteger)
      ++X showAllElements n

    showAll?: () -> B
      ++ showAll?() returns true if all computed entries of streams
      ++ will be displayed.
      --!! this should be a function of one argument
  setrest_!: (%,I,%) -> %
    ++ setrest!(x,n,y) sets rest(x,n) to y. The function will expand
    ++ cycles if necessary.
    ++
    ++X p:=[i for i in 1..]
    ++X q:=[i for i in 9..]
    ++X setrest!(p,4,q)
    ++X p

  generate: (() -> S) -> %
    ++ generate(f) creates an infinite stream all of whose elements are
    ++ equal to \spad{f()}.
    ++ Note: \spad{generate(f) = [f(),f(),f(),...]}.
    ++
    ++X f():Integer == 1
    ++X generate(f)
```

```
    generate: (S -> S,S) -> %
      ++ generate(f,x) creates an infinite stream whose first element is
      ++ x and whose nth element (\spad{n > 1}) is f applied to the previous
      ++ element. Note: \spad{generate(f,x) = [x,f(x),f(f(x)),...]}.
      ++
      ++X f(x:Integer):Integer == x+10
      ++X generate(f,10)

    filterWhile: (S -> Boolean,%) -> %
      ++ filterWhile(p,s) returns \spad{[x0,x1,...,x(n-1)]} where
      ++ \spad{s = [x0,x1,x2,..]} and
      ++ n is the smallest index such that \spad{p(xn) = false}.
      ++
      ++X m:=[i for i in 1..]

— String.help —

```
=====================================================================
String examples
=====================================================================
```

```
The type String provides character strings.  Character strings
provide all the operations for a one-dimensional array of characters,
plus additional operations for manipulating text.

String values can be created using double quotes.

  hello := "Hello, I'm AXIOM!"
    "Hello, I'm AXIOM!"
                                Type: String

Note, however, that double quotes and underscores must be preceded by
an extra underscore.

  said := "Jane said, \_"Look!\_""
    "Jane said, \"Look!\""
                                Type: String

  saw := "She saw exactly one underscore: \_\_."
    "She saw exactly one underscore: \\."
                                Type: String

It is also possible to use new to create a string of any size filled
with a given character.  Since there are many new functions it is
necessary to indicate the desired type.

  gasp: String := new(32, char "x")
    "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
                                Type: String

The length of a string is given by #.

  #gasp
    32
                                Type: PositiveInteger

Indexing operations allow characters to be extracted or replaced in strings.
For any string s, indices lie in the range 1..#s.

  hello.2
    e
                                Type: Character

Indexing is really just the application of a string to a subscript, so
any application syntax works.

  hello 2
    e
                                Type: Character
```

```
  hello(2)
    e
                                Type: Character
```

If it is important not to modify a given string, it should be copied before any updating operations are used.

```
  hullo := copy hello
    "Hello, I'm AXIOM!"
                                Type: String

  hullo.2 := char "u"; [hello, hullo]
    ["Hello, I'm AXIOM!","Hullo, I'm AXIOM!"]
                                Type: List String
```

Operations are provided to split and join strings. The concat operation allows several strings to be joined together.

```
  saidsaw := concat ["alpha","---","omega"]
    "alpha---omega"
                                Type: String
```

There is a version of concat that works with two strings.

```
  concat("hello ","goodbye")
    "hello goodbye"
                                Type: String
```

Juxtaposition can also be used to concatenate strings.

```
  "This " "is " "several " "strings " "concatenated."
    "This is several strings concatenated."
                                Type: String
```

Substrings are obtained by giving an index range.

```
  hello(1..5)
    "Hello"
                                Type: String

  hello(8..)
    "I'm AXIOM!"
                                Type: String
```

A string can be split into several substrings by giving a separation character or character class.

```
  split(hello, char " ")
    ["Hello,","I'm","AXIOM!"]
                                Type: List String
```

```
  other := complement alphanumeric();
                                Type: CharacterClass

  split(saidsaw, other)
    ["alpha","omega"]
                                Type: List String
```

Unwanted characters can be trimmed from the beginning or end of a string using the operations trim, leftTrim and rightTrim.

```
  trim("## ++ relax ++ ##", char "#")
    " ++ relax ++ "
                                Type: String
```

Each of these functions takes a string and a second argument to specify the characters to be discarded.

```
  trim("## ++ relax ++ ##", other)
    "relax"
                                Type: String
```

The second argument can be given either as a single character or as a character class.

```
  leftTrim("## ++ relax ++ ##", other)
    "relax ++ ##"
                                Type: String

  rightTrim("## ++ relax ++ ##", other)
    "## ++ relax"
                                Type: String
```

Strings can be changed to upper case or lower case using the operations upperCase and lowerCase.

```
  upperCase hello
    "HELLO, I'M AXIOM!"
                                Type: String
```

The versions with the exclamation mark change the original string, while the others produce a copy.

```
  lowerCase hello
    "hello, i'm axiom!"
                                Type: String
```

Some basic string matching is provided. The function prefix? tests whether one string is an initial prefix of another.

```
  prefix?("He", "Hello")
    true
                                Type: Boolean

  prefix?("Her", "Hello")
    false
                                Type: Boolean
```

A similar function, suffix?, tests for suffixes.

```
  suffix?("", "Hello")
    true
                                Type: Boolean

  suffix?("LO", "Hello")
    false
                                Type: Boolean
```

The function substring? tests for a substring given a starting position.

```
  substring?("ll", "Hello", 3)
    true
                                Type: Boolean

  substring?("ll", "Hello", 4)
    false
                                Type: Boolean
```

A number of position functions locate things in strings. If the first argument to position is a string, then position(s,t,i) finds the location of s as a substring of t starting the search at position i.

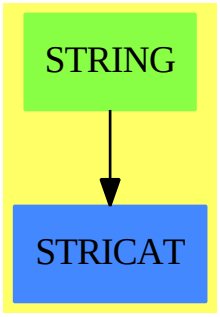
```
  n := position("nd", "underground", 1)
    2
                                Type: PositiveInteger

  n := position("nd", "underground", n+1)
    10
                                Type: PositiveInteger
```

If s is not found, then 0 is returned (minIndex(s)-1 in IndexedString).

```
  n := position("nd", "underground", n+1)
    0
                                Type: NonNegativeInteger
```

To search for a specific character or a member of a character class, a different first argument is used.



```
  position(char "d", "underground", 1)
```

```
    3
                                Type: PositiveInteger

  position(hexDigit(), "underground", 1)
    3
                                Type: PositiveInteger

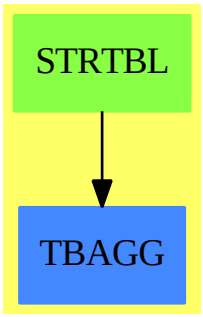
=====================================================================
StringTable examples
=====================================================================

This domain provides a table type in which the keys are known to be strings
so special techniques can be used.  Other than performance, the type
StringTable(S) should behave exactly the same way as Table(String,S).

This creates a new table whose keys are strings.

  t: StringTable(Integer) := table()
    table()
                               Type: StringTable Integer

The value associated with each string key is the number of characters
in the string.



for s in split("My name is Ian Watt.",char " ")
  repeat
    t.s := #s
                               Type: Void

  for key in keys t repeat output [key, t.key]
   ["Watt.",5]
   ["Ian",3]
```

```
   ["is",2]
   ["name",4]
   ["My",2]
                                   Type: Void

———-

domain SUBSPACE SubSpace

The first argument n is the dimension of the subSpace

The SubSpace domain is implemented as a tree. The root of the tree is the only node in which the field dataList - which points to a list of points over the ring, R - is defined. The children of the root are the top level components of the SubSpace (in 2D, these would be separate curves; in 3D, these would be separate surfaces).

The pt field is only defined in the leaves.

By way of example, consider a three dimensional subspace with two components - a three by three grid and a sphere. The internal representation of this subspace is a tree with a depth of three.

The root holds a list of all the points used in the subspace (so, if the grid and the sphere share points, the shared points would not be represented redundantly but would be referenced by index).

The root, in this case, has two children - the first points to the grid component and the second to the sphere component. The grid child has four children of its own - a 3x3 grid has 4 endpoints - and each of these point to a list of four points. To see it another way, the grid (child of the root) holds a list of line components which, when placed one above the next, forms a grid. Each of these line components is a list of points.

Points could be explicitly added to subspaces at any level. A path could be given as an argument to the addPoint() function. It is a list of NonNegativeIntegers and refers, in order, to the n-th child of the current node. For example,

```
addPoint(s,[2,3],p)
```

would add the point p to the subspace s by going to the second child of the root and then the third child of that node. If the path does extend to the full depth of the tree, nodes are automatically added so that the tree is of constant depth down any path. By not specifying the full path, new components could be added - e.g. for s from SubSpace(3,Float)

```
addPoint(s,[],p)
```

would create a new child to the root (a new component in N-space) and extend a path to a leaf of depth 3 that points to the data held in p. The subspace s would now have a new component which has one child which, in turn, has one child (the leaf). The new component is then a point.

  ++ merge(s1,s2) the subspaces s1 and s2 into a single subspace.
merge          : List % -> %
  ++ merge(ls) a list of subspaces, ls, into one subspace.
separate       : % -> List %
  ++ separate(s) makes each of the components of the \spadtype{SubSpace},
  ++ s, into a list of separate and distinct subspaces and returns
  ++ the list.
addPoint       : (%,List NNI,POINT) -> %
  ++ addPoint(s,li,p) adds the 4 dimensional point, p, to the 3
  ++ dimensional subspace, s. The list of non negative integers, li,
  ++ dictates the path to follow, or, to look at it another way,
  ++ points to the component in which the point is to be added.  It's
  ++ length should range from 0 to \spad{n - 1} where n is the dimension
  ++ of the subspace. If the length is \spad{n - 1}, then a specific
  ++ lowest level component is being referenced.  If it is less than
  ++ \spad{n - 1}, then some higher level component (0 indicates top
  ++ level component) is being referenced and a component of that level
  ++ with the desired point is created.  The subspace s is returned
  ++ with the additional point.
addPoint2      : (%,POINT) -> %
  ++ addPoint2(s,p) adds the 4 dimensional point, p, to the 3
  ++ dimensional subspace, s.
  ++ The subspace s is returned with the additional point.
addPointLast   : (%,%,POINT, NNI) -> %
  ++ addPointLast(s,s2,li,p) adds the 4 dimensional point, p, to the 3
  ++ dimensional subspace, s. s2 point to the end of the subspace
  ++ s. n is the path in the s2 component.
  ++ The subspace s is returned with the additional point.
modifyPoint    : (%,List NNI,POINT) -> %
  ++ modifyPoint(s,li,p) replaces an existing point in the 3 dimensional
```

```
    ++ subspace, s, with the 4 dimensional point, p.  The list of non
    ++ negative integers, li, dictates the path to follow, or, to look at
    ++ it another way, points to the component in which the existing point
    ++ is to be modified.  An error message occurs if s is empty, otherwise
    ++ the subspace s is returned with the point modification.
  addPoint       : (%,List NNI,NNI) -> %
    ++ addPoint(s,li,i) adds the 4 dimensional point indicated by the
    ++ index location, i, to the 3 dimensional subspace, s. The list of
    ++ non negative integers, li, dictates the path to follow, or, to
    ++ look at it another way, points to the component in which the point
    ++ is to be added.  It's length should range from 0 to \spad{n - 1}
    ++ where n is the dimension of the subspace. If the length is
    ++ \spad{n - 1}, then a specific lowest level component is being
    ++ referenced.  If it is less than \spad{n - 1}, then some higher
    ++ level component (0 indicates top level component) is being
    ++ referenced and a component of that level with the desired point
    ++ is created.  The subspace s is returned with the additional point.
  modifyPoint    : (%,List NNI,NNI) -> %
    ++ modifyPoint(s,li,i) replaces an existing point in the 3 dimensional
    ++ subspace, s, with the 4 dimensional point indicated by the index
    ++ location, i.  The list of non negative integers, li, dictates
    ++ the path to follow, or, to look at it another way, points to the
    ++ component in which the existing point is to be modified.  An error
    ++ message occurs if s is empty, otherwise the subspace s is returned
    ++ with the point modification.
  addPoint       : (%,POINT) -> NNI
    ++ addPoint(s,p) adds the point, p, to the 3 dimensional subspace, s,
    ++ and returns the new total number of points in s.
  modifyPoint    : (%,NNI,POINT) -> %
    ++ modifyPoint(s,ind,p) modifies the point referenced by the index
    ++ location, ind, by replacing it with the point, p in the 3 dimensional
    ++ subspace, s.  An error message occurs if s is empty, otherwise the
    ++ subspace s is returned with the point modification.

  closeComponent : (%,List NNI,B)     -> %
    ++ closeComponent(s,li,b) sets the property of the component in the
    ++ 3 dimensional subspace, s, to be closed if b is true, or open if
    ++ b is false.  The list of non negative integers, li, dictates the
    ++ path to follow, or, to look at it another way, points to the
    ++ component whose closed property is to be set.  The subspace, s,
    ++ is returned with the component property modification.
  defineProperty : (%,List NNI,PROP)  -> %
    ++ defineProperty(s,li,p) defines the component property in the
    ++ 3 dimensional subspace, s, to be that of p, where p is of the
    ++ domain \spadtype{SubSpaceComponentProperty}.  The list of non
    ++ negative integers, li, dictates the path to follow, or, to look
    ++ at it another way, points to the component whose property is
    ++ being defined.  The subspace, s, is returned with the component
    ++ property definition.
  traverse       : (%,List NNI) -> %
```

```
    ++ traverse(s,li) follows the branch list of the 3 dimensional
    ++ subspace, s, along the path dictated by the list of non negative
    ++ integers, li, which points to the component which has been
    ++ traversed to.  The subspace, s, is returned, where s is now
    ++ the subspace pointed to by li.
  extractPoint    : %  -> POINT
    ++ extractPoint(s) returns the point which is given by the current
    ++ index location into the point data field of the 3 dimensional
    ++ subspace s.
  extractIndex    : % -> NNI
    ++ extractIndex(s) returns a non negative integer which is the current
    ++ index of the 3 dimensional subspace s.
  extractClosed   : %  -> B
    ++ extractClosed(s) returns the \spadtype{Boolean} value of the closed
    ++ property for the indicated 3 dimensional subspace s.  If the
    ++ property is closed, \spad{True} is returned, otherwise \spad{False}
    ++ is returned.
  extractProperty : %  -> PROP
    ++ extractProperty(s) returns the property of domain
    ++ \spadtype{SubSpaceComponentProperty} of the indicated 3 dimensional
    ++ subspace s.
  level           : % -> NNI
    ++ level(s) returns a non negative integer which is the current
    ++ level field of the indicated 3 dimensional subspace s.
  parent          : % -> %
    ++ parent(s) returns the subspace which is the parent of the indicated
    ++ 3 dimensional subspace s.  If s is the top level subspace an error
    ++ message is returned.
  pointData       : % -> L POINT
    ++ pointData(s) returns the list of points from the point data field
    ++ of the 3 dimensional subspace s.

— Symbol.help —

```
=====================================================================
Symbol examples
=====================================================================

Symbols are one of the basic types manipulated by Axiom.  The
Symbol domain provides ways to create symbols of many varieties.

The simplest way to create a symbol is to "single quote" an identifier.

  X: Symbol := 'x
    x
                                    Type: Symbol

This gives the symbol even if x has been assigned a value.  If x has
not been assigned a value, then it is possible to omit the quote.

  XX: Symbol := x
    x
                                    Type: Symbol

Declarations must be used when working with symbols, because otherwise
the interpreter tries to place values in a more specialized type Variable.

  A := 'a
    a
                                    Type: Variable a

  B := b
    b
                                    Type: Variable b
```

The normal way of entering polynomials uses this fact.

```
x**2 + 1
   2
  x  + 1
                                  Type: Polynomial Integer
```

Another convenient way to create symbols is to convert a string.
This is useful when the name is to be constructed by a program.

```
"Hello"::Symbol
  Hello
                                  Type: Symbol
```

Sometimes it is necessary to generate new unique symbols, for example,
to name constants of integration. The expression new() generates a
symbol starting with %.

```
new()$Symbol
  %A
                                  Type: Symbol
```

Successive calls to new produce different symbols.

```
new()$Symbol
  %B
                                  Type: Symbol
```

The expression new("s") produces a symbol starting with %s.

```
new("xyz")$Symbol
  %xyz0
                                  Type: Symbol
```

A symbol can be adorned in various ways. The most basic thing is
applying a symbol to a list of subscripts.

```
X[i,j]
   x
    i,j
                                  Type: Symbol
```

Somewhat less pretty is to attach subscripts, superscripts or arguments.

```
U := subscript(u, [1,2,1,2])
   u
    1,2,1,2
                                  Type: Symbol
```

```
V := superscript(v, [n])
```

```
     n
    v
                                    Type: Symbol

  P := argscript(p, [t])
    p(t)
                                    Type: Symbol
```

It is possible to test whether a symbol has scripts using the scripted? test.

```
  scripted? U
    true
                                    Type: Boolean

  scripted? X
    false
                                    Type: Boolean
```

If a symbol is not scripted, then it may be converted to a string.

```
  string X
    "x"
                                    Type: String
```

The basic parts can always be extracted using the name and scripts operations.

```
  name U
    u
                                    Type: Symbol

  scripts U
    [sub= [1,2,1,2],sup= [],presup= [],presub= [],args= []]
                 Type: Record(sub: List OutputForm,
                              sup: List OutputForm,
                              presup: List OutputForm,
                              presub: List OutputForm,
                              args: List OutputForm)

  name X
    x
                                    Type: Symbol

  scripts X
    [sub= [],sup= [],presup= [],presub= [],args= []]
                 Type: Record(sub: List OutputForm,
                              sup: List OutputForm,
                              presup: List OutputForm,
                              presub: List OutputForm,
                              args: List OutputForm)
```

```
The most general form is obtained using the script operation.  This
operation takes an argument which is a list containing, in this order,
lists of subscripts, superscripts, presuperscripts, presubscripts and
arguments to a symbol.

  M := script(Mammoth, [ [i,j],[k,l],[0,1],[2],[u,v,w] ])
     0,1       k,l
        Mammoth   (u,v,w)
       2       i,j
                                    Type: Symbol

  scripts M
    [sub= [i,j],sup= [k,l],presup= [0,1],presub= [2],args= [u,v,w]]
                  Type: Record(sub: List OutputForm,
                               sup: List OutputForm,
                               presup: List OutputForm,
                               presub: List OutputForm,
                               args: List OutputForm)

If trailing lists of scripts are omitted, they are assumed to be empty.

  N := script(Nut, [ [i,j],[k,l],[0,1] ])
     0,1   k,l
        Nut
           i,j
                                    Type: Symbol

  scripts N
    [sub= [i,j],sup= [k,l],presup= [0,1],presub= [],args= []]
                  Type: Record(sub: List OutputForm,
                               sup: List OutputForm,
                               presup: List OutputForm,
                               presub: List OutputForm,
                               args: List OutputForm)

++ Basic and scripted symbols.

Symbol(): Exports == Implementation where
  L ==> List OutputForm
  Scripts ==> Record(sub:L,sup:L,presup:L,presub:L,args:L)

  Exports ==> Join(OrderedSet, ConvertibleTo InputForm, OpenMath,
        ConvertibleTo Symbol,
         ConvertibleTo Pattern Integer, ConvertibleTo Pattern Float,
          PatternMatchable Integer, PatternMatchable Float) with
     new: () -> %
       ++ new() returns a new symbol whose name starts with %.
     new: % -> %
       ++ new(s) returns a new symbol whose name starts with %s.
     resetNew: () -> Void
       ++ resetNew() resets the internals counters that new() and
       ++ new(s) use to return distinct symbols every time.
     coerce: String -> %
       ++ coerce(s) converts the string s to a symbol.
     name: % -> %
```

```
      ++ name(s) returns s without its scripts.
    scripted?: % -> Boolean
      ++ scripted?(s) is true if s has been given any scripts.
    scripts: % -> Scripts
      ++ scripts(s) returns all the scripts of s.
    script: (%, List L) -> %
      ++ script(s, [a,b,c,d,e]) returns s with subscripts a,
      ++ superscripts b, pre-superscripts c, pre-subscripts d,
      ++ and argument-scripts e.  Omitted components are taken to be empty.
      ++ For example, \spad{script(s, [a,b,c])} is equivalent to
      ++ \spad{script(s,[a,b,c,[],[]])}.
    script: (%, Scripts) -> %
      ++ script(s, [a,b,c,d,e]) returns s with subscripts a,
      ++ superscripts b, pre-superscripts c, pre-subscripts d,
      ++ and argument-scripts e.
    subscript: (%, L) -> %
      ++ subscript(s, [a1,...,an]) returns s
      ++ subscripted by \spad{[a1,...,an]}.
    superscript: (%, L) -> %
      ++ superscript(s, [a1,...,an]) returns s
      ++ superscripted by \spad{[a1,...,an]}.
    argscript: (%, L) -> %
      ++ argscript(s, [a1,...,an]) returns s
      ++ arg-scripted by \spad{[a1,...,an]}.
    elt: (%, L) -> %
      ++ elt(s,[a1,...,an]) or s([a1,...,an]) returns s subscripted by \spad{[a1,...,an]}.
    string: % -> String
      ++ string(s) converts the symbol s to a string.
      ++ Error: if the symbol is subscripted.
    list: % -> List %
      ++ list(sy) takes a scripted symbol and produces a list
      ++ of the name followed by the scripts.
    sample: constant -> %
      ++ sample() returns a sample of %

++ Author: Mike Dewar
++ Date Created:  October 1992
++ Date Last Updated: 12 July 1994
++ Description:
++ Create and manipulate a symbol table for generated FORTRAN code

SymbolTable() : exports == implementation where

  T   ==> Union(S:Symbol,P:Polynomial Integer)
  TL1 ==> List T
  TU  ==> Union(name:Symbol,bounds:TL1)
  TL  ==> List TU
  SEX ==> SExpression
  OFORM ==> OutputForm
  L   ==> List
  FSTU ==> Union(fst:FortranScalarType,void:"void")

  exports ==> CoercibleTo OutputForm with
    coerce : $ -> Table(Symbol,FortranType)
      ++ coerce(x) returns a table view of x
    empty  : () -> $
      ++ empty() returns a new, empty symbol table
    declare! : (L Symbol,FortranType,$) -> FortranType
```

```
    ++ declare!(l,t,tab) creates new entrys in tab, declaring each of l
    ++ to be of type t
  declare! : (Symbol,FortranType,$) -> FortranType
    ++ declare!(u,t,tab) creates a new entry in tab, declaring u to be of
    ++ type t
  fortranTypeOf : (Symbol,$) -> FortranType
    ++ fortranTypeOf(u,tab) returns the type of u in tab
  parametersOf: $ -> L Symbol
    ++ parametersOf(tab) returns a list of all the symbols declared in tab
  typeList : (FortranScalarType,$) -> TL
    ++ typeList(t,tab) returns a list of all the objects of type t in tab
  externalList : $ -> L Symbol
    ++ externalList(tab) returns a list of all the external symbols in tab
  typeLists : $ -> L TL
    ++ typeLists(tab) returns a list of lists of types of objects in tab
  newTypeLists : $ -> SEX
    ++ newTypeLists(x) is not documented
  printTypes: $ -> Void
    ++ printTypes(tab) produces FORTRAN type declarations from tab, on the
    ++ current FORTRAN output stream
  symbolTable: L Record(key:Symbol,entry:FortranType) -> $
    ++ symbolTable(l) creates a symbol table from the elements of l.

— Table.help —

```
=====================================================================
Table examples
=====================================================================

The Table constructor provides a general structure for associative
storage.  This type provides hash tables in which data objects can be
saved according to keys of any type.  For a given table, specific
types must be chosen for the keys and entries.

In this example the keys to the table are polynomials with integer
coefficients.  The entries in the table are strings.

  t: Table(Polynomial Integer, String) := table()
    table()
                               Type: Table(Polynomial Integer,String)

To save an entry in the table, the setelt operation is used.  This can
be called directly, giving the table a key and an entry.
```

```
  setelt(t, x**2 - 1, "Easy to factor")
    "Easy to factor"
                                Type: String
```

Alternatively, you can use assignment syntax.

```
  t(x**3 + 1) := "Harder to factor"
    "Harder to factor"
                                Type: String

  t(x) := "The easiest to factor"
    "The easiest to factor"
                                Type: String
```

Entries are retrieved from the table by calling the elt operation.

```
  elt(t, x)
    "The easiest to factor"
                                Type: String
```

This operation is called when a table is "applied" to a key using this or the following syntax.

```
  t.x
    "The easiest to factor"
                                Type: String

  t x
    "The easiest to factor"
                                Type: String
```

Parentheses are used only for grouping. They are needed if the key is an infixed expression.

```
  t.(x**2 - 1)
    "Easy to factor"
                                Type: String
```

Note that the elt operation is used only when the key is known to be in the table, otherwise an error is generated.

```
  t (x**3 + 1)
    "Harder to factor"
                                Type: String
```

You can get a list of all the keys to a table using the keys operation.

```
  keys t
        3      2
    [x,x  + 1,x  - 1]
```

```
                                Type: List Polynomial Integer
```

If you wish to test whether a key is in a table, the search operation is used. This operation returns either an entry or "failed".

```
  search(x, t)
    "The easiest to factor"
                                Type: Union(String,...)

  search(x**2, t)
    "failed"
                                Type: Union("failed",...)
```

The return type is a union so the success of the search can be tested using case.

```
  search(x**2, t) case "failed"
    true
                                Type: Boolean
```

The remove operation is used to delete values from a table.

```
  remove!(x**2-1, t)
    "Easy to factor"
                                Type: Union(String,...)
```

If an entry exists under the key, then it is returned. Otherwise remove returns "failed".

```
  remove!(x-1, t)
    "failed"
                                Type: Union("failed",...)
```

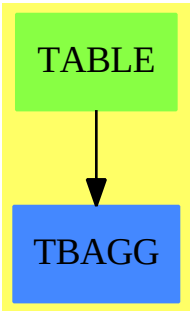
The number of key-entry pairs can be found using the # operation.

```
  #t
    2
                                Type: PositiveInteger
```

Just as keys returns a list of keys to the table, a list of all the entries can be obtained using the members operation.

```
  members t
   (17)  ["The easiest to factor","Harder to factor"]
                                Type: List String
```

A number of useful operations take functions and map them on to the table to compute the result. Here we count the entries which have "Hard" as a prefix.



```
  count(s: String +-> prefix?("Hard", s), t)
    1
                                Type: PositiveInteger

Other table types are provided to support various needs.
  o AssociationList gives a list with a table view. This allows new
    entries to be appended onto the front of the list to cover up old
    entries. This is useful when table entries need to be stacked or when
    frequent list traversals are required.
  o EqTable gives tables in which keys are considered equal only when
    they are in fact the same instance of a structure.
  o StringTable should be used when the keys are known to be strings.
  o SparseTable provides tables with default entries, so lookup never fails.
    The GeneralSparseTable constructor can be used to make any table type
    behave this way.
  o KeyedAccessFile allows values to be saved in a file, accessed as a table.

— domain TS TaylorSeries —

```
)abbrev domain TS TaylorSeries
++ Authors: Burge, Watt, Williamson
++ Date Created: 15 August 1988
++ Date Last Updated: 18 May 1991
++ Description:
++ \spadtype{TaylorSeries} is a general multivariate Taylor series domain
++ over the ring Coef and with variables of type Symbol.

TaylorSeries(Coef): Exports == Implementation where
  Coef  : Ring
  L   ==> List
  NNI ==> NonNegativeInteger
  SMP ==> Polynomial Coef
  StS ==> Stream SMP

  Exports ==> MultivariateTaylorSeriesCategory(Coef,Symbol) with
    coefficient: (%,NNI) -> SMP
      ++\spad{coefficient(s, n)} gives the terms of total degree n.
    coerce: Symbol -> %
      ++\spad{coerce(s)} converts a variable to a Taylor series
    coerce: SMP -> %
      ++\spad{coerce(s)} regroups terms of s by total degree
      ++ and forms a series.

    if Coef has Algebra Fraction Integer then
      integrate: (%,Symbol,Coef) -> %
        ++\spad{integrate(s,v,c)} is the integral of s with respect
        ++ to v and having c as the constant of integration.
      fintegrate: (() -> %,Symbol,Coef) -> %
        ++\spad{fintegrate(f,v,c)} is the integral of \spad{f()} with respect
        ++ to v and having c as the constant of integration.
```

```
       ++ The evaluation of \spad{f()} is delayed.

  Implementation ==> SparseMultivariateTaylorSeries(Coef,Symbol,SMP) add
    Rep := StS -- Below we use the fact that Rep of PS is Stream SMP.

    polynomial(s,n) ==
      sum : SMP := 0
      for i in 0..n while not empty? s repeat
        sum := sum + frst s
        s:= rst s
      sum
```

domain TEX TexFormat

product(product(i*j,i=a..b),j=c..d) fix

The expression prints properly in ascii text but the tex output is incorrect. Originally the input

```
product(product(i*j,i=a..b),j=c..d)
```

prints as

$$PI2\,(j = c,\ d,\ PI2\,(i = a,\ b,\ i\ j)) \tag{1}$$

but now says: The problem is in [[src/algebra/tex.spad.pamphlet]] in the list of constants. The code used to read

```
    plexOps       : L S := ["SIGMA","SIGMA2","PI","INTSIGN","INDEFINTEGRAL"]$(L S)
    plexPrecs     : L I := [    700, 800,      700,            700]$(L I)
```

it now reads:

— **product(product(i*j,i=a..b),j=c..d) fix** —

```
    plexOps       : L S := ["SIGMA","SIGMA2","PI","PI2","INTSIGN","INDEFINTEGRAL"]$(L S)
    plexPrecs     : L I := [    700, 800,     700, 800 , 700,      700]$(L I)
```

———-

in addition we need to add a line defining [[PI2]] in [[formatPlex]]:

— **define PI2** —

```
        op = "PI2"     => "\prod"
```

———-

— **TexFormat.input** —

```

========================================================================
TexFormat examples
========================================================================

You can ask Axiom to show latex output. In particular, this can be
used for complex output.

(1/2)::TEX

     ["$$","\frac{1}{2} ","$$"]
```

```
(1/(x+5))::TEX

     ["$$","\frac{1}{{x+5}} ","$$"]

((x+3)/(y-5))::TEX

     ["$$","\frac{{x+3}}{{y -5}} ","$$"]

We can change the fraction display so it is horizontal:

)set output fraction horizontal

(1/2)::TEX

     ["$$","SLASH ","\left(","{1, \: 2} ","\right)","$$"]

(1/(x+5))::TEX

     ["$$","SLASH ","\left(","{1, \: {x+5}} ","\right)","$$"]

((x+3)/(y-5))::TEX

     ["$$","SLASH ","\left(","{{x+3}, \: {y -5}} ","\right)","$$"]

See Also:
o )show TexFormat
```

— domain TEX TexFormat —

```
)abbrev domain TEX TexFormat
++ Author: Robert S. Sutor
++ Date Created: 1987 through 1992
++ Description:
++ \spadtype{TexFormat} provides a coercion from \spadtype{OutputForm} to
++ \TeX{} format.  The particular dialect of \TeX{} used is \LaTeX{}.
++ The basic object consists of three parts: a prologue, a
++ tex part and an epilogue. The functions \spadfun{prologue},
++ \spadfun{tex} and \spadfun{epilogue} extract these parts,
++ respectively.  The main guts of the expression go into the tex part.
++ The other parts can be set (\spadfun{setPrologue!},
++ \spadfun{setEpilogue!}) so that contain the appropriate tags for
++ printing. For example, the prologue and epilogue might simply
++ contain ``\verb+\[+'' and ``\verb+\]+'', respectively, so that
++ the TeX section will be printed in LaTeX display math mode.

TexFormat(): public == private where
  E      ==> OutputForm
  I      ==> Integer
  L      ==> List
  S      ==> String
  US     ==> UniversalSegment(Integer)

  public == SetCategory with
    coerce:   E -> $
      ++ coerce(o) changes o in the standard output format to TeX
      ++ format.
    convert:  (E,I) -> $
      ++ convert(o,step) changes o in standard output format to
      ++ TeX format and also adds the given step number. This is useful
      ++ if you want to create equations with given numbers or have the
      ++ equation numbers correspond to the interpreter step numbers.
    convert:  (E,I,E) -> $
      ++ convert(o,step,type) changes o in standard output format to
      ++ TeX format and also adds the given step number and type. This
      ++ is useful if you want to create equations with given numbers
      ++ or have the equation numbers correspond to the interpreter step
      ++ numbers.
    display:  ($, I) -> Void
      ++ display(t,width) outputs the TeX formatted code t so that each
      ++ line has length less than or equal to \spadvar{width}.
    display:  $ -> Void
      ++ display(t) outputs the TeX formatted code t so that each
```

```
    ++ line has length less than or equal to the value set by
    ++ the system command \spadsyscom{set output length}.
  epilogue: $ -> L S
    ++ epilogue(t) extracts the epilogue section of a TeX form t.
  tex:      $ -> L S
    ++ tex(t) extracts the TeX section of a TeX form t.
  new:      () -> $
    ++ new() create a new, empty object. Use \spadfun{setPrologue!},
    ++ \spadfun{setTex!} and \spadfun{setEpilogue!} to set the various
    ++ components of this object.
  prologue: $ -> L S
    ++ prologue(t) extracts the prologue section of a TeX form t.
  setEpilogue!: ($, L S) -> L S
    ++ setEpilogue!(t,strings) sets the epilogue section of a TeX form t
    ++ to strings.
  setTex!:  ($, L S) -> L S
    ++ setTex!(t,strings) sets the TeX section of a TeX form t to strings.
  setPrologue!: ($, L S) -> L S
    ++ setPrologue!(t,strings) sets the prologue section of a TeX form t
    ++ to strings.

====================================================================
TextFile examples
====================================================================

The domain TextFile allows Axiom to read and write character data and
exchange text with other programs.  This type behaves in Axiom much
like a File of strings, with additional operations to cause new lines.
We give an example of how to produce an upper case copy of a file.
```

```
This is the file from which we read the text.

  f1: TextFile := open("/etc/group", "input")
    "/etc/group"
                                Type: TextFile

This is the file to which we write the text.

  f2: TextFile := open("/tmp/MOTD", "output")
    "MOTD"
                                Type: TextFile

Entire lines are handled using the readLine and writeLine operations.

  l := readLine! f1
    "root:x:0:root"
                                Type: String

  writeLine!(f2, upperCase l)
    "ROOT:X:0:ROOT"
                                Type: String

Use the endOfFile? operation to check if you have reached the end of the file.

  while not endOfFile? f1 repeat
    s := readLine! f1
    writeLine!(f2, upperCase s)
                                Type: Void

The file f1 is exhausted and should be closed.

  close! f1
    "/etc/group"
                                Type: TextFile

It is sometimes useful to write lines a bit at a time.  The write operation
allows this.

  write!(f2, "-The-")
    "-The-"
                                Type: String

  write!(f2, "-End-")
    "-End-"
                                Type: String

This ends the line.  This is done in a machine-dependent manner.

  writeLine! f2
    ""
```

```
                                Type: String

  close! f2
    "MOTD"
                                Type: TextFile

Finally, clean up.

  )system rm /tmp/MOTD

— domain TEXTFILE TextFile —

```
)abbrev domain TEXTFILE TextFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides an implementation of text files.  Text is stored
++ in these files using the native character set of the computer.

TextFile: Cat == Def where
    StreamName ==> Union(FileName, "console")

    Cat == FileCategory(FileName, String) with
        writeLine_!: (%, String) -> String
          ++ writeLine!(f,s) writes the contents of the string s
          ++ and finishes the current line in the file f.
          ++ The value of s is returned.

        writeLine_!: % -> String
          ++ writeLine!(f) finishes the current line in the file f.
          ++ An empty string is returned.  The call \spad{writeLine!(f)} is
          ++ equivalent to \spad{writeLine!(f,"")}.

        readLine_!: % -> String
          ++ readLine!(f) returns a string of the contents of a line from
          ++ the file f.

        readLineIfCan_!: % -> Union(String, "failed")
          ++ readLineIfCan!(f) returns a string of the contents of a line from
          ++ file f, if possible.  If f is not readable or if it is
          ++ positioned at the end of file, then \spad{"failed"} is returned.

        readIfCan_!: % -> Union(String, "failed")
          ++ readIfCan!(f) returns a string of the contents of a line from
          ++ file f, if possible.  If f is not readable or if it is
          ++ positioned at the end of file, then \spad{"failed"} is returned.

        endOfFile?: % -> Boolean
          ++ endOfFile?(f) tests whether the file f is positioned after the
          ++ end of all text.  If the file is open for output, then
          ++ this test is always true.

    Def == File(String) add
        FileState ==> SExpression

        Rep := Record(fileName:   FileName,    _
                      fileState:  FileState,   _
                      fileIOmode: String)

  ++ title(v,s) changes the title which is shown in the three-dimensional
  ++ viewport window, v of domain \spadtype{ThreeDimensionalViewport}.
dimensions            : (%,NNI,NNI,PI,PI)                      -> Void
  ++ dimensions(v,x,y,width,height) sets the position of the
  ++ upper left-hand corner of the three-dimensional viewport, v,
  ++ which is of domain \spadtype{ThreeDimensionalViewport}, to
  ++ the window coordinate x, y, and sets the dimensions of the
  ++ window to that of \spad{width}, \spad{height}.  The new
  ++ dimensions are not displayed until the function
  ++ \spadfun{makeViewport3D} is executed again for v.
viewpoint             : (%,F,F,F,F,F)                          -> Void
  ++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
  ++ to \spad{th} radians, the latitudinal view angle to \spad{phi}
  ++ radians, the scale factor to \spad{s}, the horizontal viewport
  ++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
  ++ for the viewport v, which is of the domain
  ++ \spadtype{ThreeDimensionalViewport}.  The new viewpoint position
  ++ is not displayed until the function \spadfun{makeViewport3D} is
  ++ executed again for v.
viewpoint             : (%) -> V
  ++ viewpoint(v) returns the current viewpoint setting of the given
  ++ viewport, v.  This function is useful in the situation where the
  ++ user has created a viewport, proceeded to interact with it via
  ++ the control panel and desires to save the values of the viewpoint
```

```
  ++ as the default settings for another viewport to be created using
  ++ the system.
viewpoint : (%,V) -> Void
  ++ viewpoint(v,viewpt) sets the viewpoint for the viewport.  The
  ++ viewport record consists of the latitudal and longitudal angles,
  ++ the zoom factor, the x,y and z scales, and the x and y displacements.
viewpoint             : (%,I,I,F,F,F)                          -> Void
  ++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
  ++ to \spad{th} degrees, the latitudinal view angle to \spad{phi}
  ++ degrees, the scale factor to \spad{s}, the horizontal viewport
  ++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
  ++ for the viewport v, which is of the domain
  ++ \spadtype{ThreeDimensionalViewport}.  The new viewpoint position
  ++ is not displayed until the function \spadfun{makeViewport3D} is
  ++ executed again for v.
viewpoint             : (%,F,F)                                -> Void
  ++ viewpoint(v,th,phi) sets the longitudinal view angle to \spad{th}
  ++ radians and the latitudinal view angle to \spad{phi} radians
  ++ for the viewport v, which is of the domain
  ++ \spadtype{ThreeDimensionalViewport}.  The new viewpoint position
  ++ is not displayed until the function \spadfun{makeViewport3D} is
  ++ executed again for v.
viewpoint             : (%,F,F,F)                              -> Void
  ++ viewpoint(v,rotx,roty,rotz) sets the rotation about the x-axis
  ++ to be \spad{rotx} radians, sets the rotation about the y-axis
  ++ to be \spad{roty} radians, and sets the rotation about the z-axis
  ++ to be \spad{rotz} radians, for the viewport v, which is of the
  ++ domain \spadtype{ThreeDimensionalViewport} and displays v with
  ++ the new view position.
controlPanel          : (%,S)                                  -> Void
  ++ controlPanel(v,s) displays the control panel of the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}, if s is "on", or hides
  ++ the control panel if s is "off".
axes                  : (%,S)                                  -> Void
  ++ axes(v,s) displays the axes of the given three-dimensional
  ++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport},
  ++ if s is "on", or does not display the axes if s is "off".
diagonals             : (%,S)                                  -> Void
  ++ diagonals(v,s) displays the diagonals of the polygon outline
  ++ showing a triangularized surface instead of a quadrilateral
  ++ surface outline, for the given three-dimensional viewport v
  ++ which is of domain \spadtype{ThreeDimensionalViewport}, if s is
  ++ "on", or does not display the diagonals if s is "off".
outlineRender         : (%,S)                                  -> Void
  ++ outlineRender(v,s) displays the polygon outline showing either
  ++ triangularized surface or a quadrilateral surface outline depending
  ++ on the whether the \spadfun{diagonals} function has been set, for
  ++ the given three-dimensional viewport v which is of domain
  ++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
```

```
  ++ display the polygon outline if s is "off".
drawStyle             : (%,S)                                    -> Void
  ++ drawStyle(v,s) displays the surface for the given three-dimensional
  ++ viewport v which is of domain \spadtype{ThreeDimensionalViewport}
  ++ in the style of drawing indicated by s.  If s is not a valid
  ++ drawing style the style is wireframe by default.  Possible
  ++ styles are \spad{"shade"}, \spad{"solid"} or \spad{"opaque"},
  ++ \spad{"smooth"}, and \spad{"wireMesh"}.
rotate                : (%,F,F)                                  -> Void
  ++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
  ++ \spad{th} radians and the latitudinal view angle \spad{phi} radians
  ++ for the viewport v, which is of the domain
  ++ \spadtype{ThreeDimensionalViewport}.
rotate                : (%,I,I)                                  -> Void
  ++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
  ++ \spad{th} degrees and the latitudinal view angle \spad{phi} degrees
  ++ for the viewport v, which is of the domain
  ++ \spadtype{ThreeDimensionalViewport}.  The new rotation position
  ++ is not displayed until the function \spadfun{makeViewport3D} is
  ++ executed again for v.
zoom                  : (%,F)                                    -> Void
  ++ zoom(v,s) sets the graph scaling factor to s, for the viewport v,
  ++ which is of the domain \spadtype{ThreeDimensionalViewport}.
zoom                  : (%,F,F,F)                                -> Void
  ++ zoom(v,sx,sy,sz) sets the graph scaling factors for the x-coordinate
  ++ axis to \spad{sx}, the y-coordinate axis to \spad{sy} and the
  ++ z-coordinate axis to \spad{sz} for the viewport v, which is of
  ++ the domain \spadtype{ThreeDimensionalViewport}.
translate             : (%,F,F)                                  -> Void
  ++ translate(v,dx,dy) sets the horizontal viewport offset to \spad{dx}
  ++ and the vertical viewport offset to \spad{dy}, for the viewport v,
  ++ which is of the domain \spadtype{ThreeDimensionalViewport}.
perspective           : (%,S)                                    -> Void
  ++ perspective(v,s) displays the graph in perspective if s is "on",
  ++ or does not display perspective if s is "off" for the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}.
eyeDistance           : (%,F)                                    -> Void
  ++ eyeDistance(v,d) sets the distance of the observer from the center
  ++ of the graph to d, for the viewport v, which is of the domain
  ++ \spadtype{ThreeDimensionalViewport}.
hitherPlane           : (%,F)                                    -> Void
  ++ hitherPlane(v,h) sets the hither clipping plane of the graph to h,
  ++ for the viewport v, which is of the domain
  ++ \spadtype{ThreeDimensionalViewport}.
showRegion            : (%,S)                                    -> Void
  ++ showRegion(v,s) displays the bounding box of the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
  ++ display the box if s is "off".
```

```
showClipRegion        : (%,S)                                    -> Void
  ++ showClipRegion(v,s) displays the clipping region of the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
  ++ display the region if s is "off".
clipSurface           : (%,S)                                    -> Void
  ++ clipSurface(v,s) displays the graph with the specified
  ++ clipping region removed if s is "on", or displays the graph
  ++ without clipping implemented if s is "off", for the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}.
lighting              : (%,F,F,F)                                -> Void
  ++ lighting(v,x,y,z) sets the position of the light source to
  ++ the coordinates x, y, and z and displays the graph for the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}.
intensity             : (%,F)                                    -> Void
  ++ intensity(v,i) sets the intensity of the light source to i, for
  ++ the given three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}.
reset                 :  %                                       -> Void
  ++ reset(v) sets the current state of the graph characteristics
  ++ of the given three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}, back to their initial settings.
colorDef              : (%,C,C)                                  -> Void
  ++ colorDef(v,c1,c2) sets the range of colors along the colormap so
  ++ that the lower end of the colormap is defined by \spad{c1} and the
  ++ top end of the colormap is defined by \spad{c2}, for the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}.
write                 : (%,S)                                    -> S
  ++ write(v,s) takes the given three-dimensional viewport, v, which
  ++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
  ++ a directory indicated by s, which contains the graph data
  ++ file for v.
write                 : (%,S,S)                                  -> S
  ++ write(v,s,f) takes the given three-dimensional viewport, v, which
  ++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
  ++ a directory indicated by s, which contains the graph data
  ++ file for v and an optional file type f.
write                 : (%,S,L S)                                -> S
  ++ write(v,s,lf) takes the given three-dimensional viewport, v, which
  ++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
  ++ a directory indicated by s, which contains the graph data
  ++ file for v and the optional file types indicated by the list lf.
close                 :  %                                       -> Void
  ++ close(v) closes the viewport window of the given
  ++ three-dimensional viewport, v, which is of domain
  ++ \spadtype{ThreeDimensionalViewport}, and terminates the
  ++ corresponding process ID.
```

```
    key                  :  %                                        -> I
      ++ key(v) returns the process ID number of the given three-dimensional
      ++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport}.

— domain TUBE TubePlot —

```
)abbrev domain TUBE TubePlot
++ Author: Clifton J. Williamson
++ Date Created: Bastille Day 1989
++ Date Last Updated: 5 June 1990
++ Description:
++ Package for constructing tubes around 3-dimensional parametric curves.
++ Domain of tubes around 3-dimensional parametric curves.

TubePlot(Curve): Exports == Implementation where
  Curve : PlottableSpaceCurveCategory
  B   ==> Boolean
  L   ==> List
  Pt  ==> Point DoubleFloat

  Exports ==> with
    getCurve: % -> Curve
```

```
      ++ getCurve(t) returns the \spadtype{PlottableSpaceCurveCategory}
      ++ representing the parametric curve of the given tube plot t.
    listLoops: % -> L L Pt
      ++ listLoops(t) returns the list of lists of points, or the 'loops',
      ++ of the given tube plot t.
    closed?: % -> B
      ++ closed?(t) tests whether the given tube plot t is closed.
    open?: % -> B
      ++ open?(t) tests whether the given tube plot t is open.
    setClosed: (%,B) -> B
      ++ setClosed(t,b) declares the given tube plot t to be closed if
      ++ b is true, or if b is false, t is set to be open.
    tube: (Curve,L L Pt,B) -> %
      ++ tube(c,ll,b) creates a tube of the domain \spadtype{TubePlot} from a
      ++ space curve c of the category \spadtype{PlottableSpaceCurveCategory},
      ++ a list of lists of points (loops) ll and a boolean b which if
      ++ true indicates a closed tube, or if false an open tube.

  Implementation ==> add

```
====================================================================
TwoDimensionalArray examples
====================================================================

The TwoDimensionalArray domain is used for storing data in a two
dimensional data structure indexed by row and by column.  Such an
array is a homogeneous data structure in that all the entries of the
array must belong to the same Axiom domain..  Each array has a fixed
number of rows and columns specified by the user and arrays are not
extensible.  In Axiom, the indexing of two-dimensional arrays is
one-based.  This means that both the "first" row of an array and the
"first" column of an array are given the index 1.  Thus, the entry
in the upper left corner of an array is in position (1,1).

The operation new creates an array with a specified number of rows and
```

```
columns and fills the components of that array with a specified entry.
The arguments of this operation specify the number of rows, the number
of columns, and the entry.

This creates a five-by-four array of integers, all of whose entries are
zero.

  arr : ARRAY2 INT := new(5,4,0)
        +0  0  0  0+
        |           |
        |0  0  0  0|
        |           |
        |0  0  0  0|
        |           |
        |0  0  0  0|
        |           |
        +0  0  0  0+
                          Type: TwoDimensionalArray Integer

The entries of this array can be set to other integers using setelt.

Issue this to set the element in the upper left corner of this array to 17.

  setelt(arr,1,1,17)
    17
                          Type: PositiveInteger

Now the first element of the array is 17.

  arr
        +17  0  0  0+
        |           |
        |0   0  0  0|
        |           |
        |0   0  0  0|
        |           |
        |0   0  0  0|
        |           |
        +0   0  0  0+
                          Type: TwoDimensionalArray Integer

Likewise, elements of an array are extracted using the operation elt.

  elt(arr,1,1)
    17
                          Type: PositiveInteger

Another way to use these two operations is as follows.  This sets the
element in position (3,2) of the array to 15.
```

```
  arr(3,2) := 15
    15
                          Type: PositiveInteger
```

This extracts the element in position (3,2) of the array.

```
  arr(3,2)
    15
                          Type: PositiveInteger
```

The operations elt and setelt come equipped with an error check which verifies that the indices are in the proper ranges. For example, the above array has five rows and four columns, so if you ask for the entry in position (6,2) with arr(6,2) Axiom displays an error message. If there is no need for an error check, you can call the operations qelt and qsetelt which provide the same functionality but without the error check. Typically, these operations are called in well-tested programs.

The operations row and column extract rows and columns, respectively, and return objects of OneDimensionalArray with the same underlying element type.

```
  row(arr,1)
    [17,0,0,0]
                          Type: OneDimensionalArray Integer

  column(arr,1)
    [17,0,0,0,0]
                          Type: OneDimensionalArray Integer
```

You can determine the dimensions of an array by calling the operations nrows and ncols, which return the number of rows and columns, respectively.

```
  nrows(arr)
    5
                          Type: PositiveInteger

  ncols(arr)
    4
                          Type: PositiveInteger
```

To apply an operation to every element of an array, use map. This creates a new array. This expression negates every element.

```
  map(-,arr)
         +- 17   0    0  0+
         |                 |
         | 0     0    0  0|
         |                 |
         | 0    - 15  0  0|
```

```
        |                |
        | 0     0    0  0|
        |                |
        + 0     0    0  0+
                           Type: TwoDimensionalArray Integer
```

This creates an array where all the elements are doubled.

```
  map((x +-> x + x),arr)
        +34  0   0  0+
        |            |
        |0   0   0  0|
        |            |
        |0   30  0  0|
        |            |
        |0   0   0  0|
        |            |
        +0   0   0  0+
                           Type: TwoDimensionalArray Integer
```

To change the array destructively, use map instead of map. If you need to make a copy of any array, use copy.

```
  arrc := copy(arr)
        +17  0   0  0+
        |            |
        |0   0   0  0|
        |            |
        |0   15  0  0|
        |            |
        |0   0   0  0|
        |            |
        +0   0   0  0+
                           Type: TwoDimensionalArray Integer

  map!(-,arrc)
        +- 17   0    0  0+
        |                |
        | 0     0    0  0|
        |                |
        | 0    - 15  0  0|
        |                |
        | 0     0    0  0|
        |                |
        + 0     0    0  0+
                           Type: TwoDimensionalArray Integer

  arrc
        +- 17   0    0  0+
        |                |
```

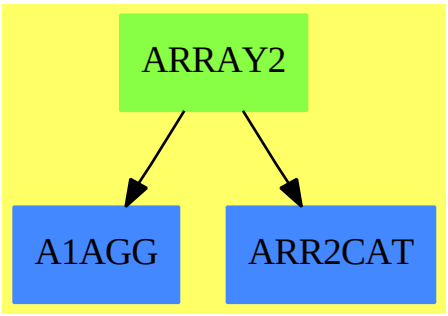
```
         | 0     0    0  0|
         |                 |
         | 0    - 15  0  0|
         |                 |
         | 0     0    0  0|
         |                 |
         + 0     0    0  0+
                          Type: TwoDimensionalArray Integer

  arr
         +17  0   0  0+
         |             |
         |0   0   0  0|
         |             |
         |0   15  0  0|
         |             |
         |0   0   0  0|
         |             |
         +0   0   0  0+
                          Type: TwoDimensionalArray Integer

Use member? to see if a given element is in an array.

  member?(17,arr)
    true
                          Type: Boolean

  member?(10317,arr)
    false
                          Type: Boolean



To see how many times an element appears in an array, use count.

  count(17,arr)
    1
                          Type: PositiveInteger

  count(0,arr)
    18
                          Type: PositiveInteger

TwoDimensionalViewport examples
========================================================================

We want to graph x^3 * (a+b*x) on the interval x=-1..1
so we clear out the workspace

We assign values to the constants
  a:=0.5
    0.5
                              Type: Float
```

```
  b:=0.5
    0.5
                              Type: Float

We draw the first case of the graph

  y1:=draw(x^3*(a+b*x),x=-1..1,title=="2.2.10 explicit")
    TwoDimensionalViewport: "2.2.10 explicit"
                              Type: TwoDimensionalViewport

We fetch the graph of the first object

  g1:=getGraph(y1,1)
    Graph with 1 point list
                              Type: GraphImage

We extract its points

  pointLists g1

Exports ==> SetCategory with
  getPickedPoints : $ -> L POINT
    ++ getPickedPoints(x)
    ++ returns a list of small floats for the points the
    ++ user interactively picked on the viewport
    ++ for full integration into the system, some design
    ++ issues need to be addressed: e.g. how to go through
    ++ the GraphImage interface, how to default to graphs, etc.
  viewport2D     : ()                                    -> $
```

```
  ++ viewport2D() returns an undefined two-dimensional viewport
  ++ of the domain \spadtype{TwoDimensionalViewport} whose
  ++ contents are empty.
makeViewport2D : $                                  -> $
  ++ makeViewport2D(v) takes the given two-dimensional viewport,
  ++ v, of the domain \spadtype{TwoDimensionalViewport} and
  ++ displays a viewport window on the screen which contains
  ++ the contents of v.
options        : $                                  -> L DROP
  ++ options(v) takes the given two-dimensional viewport, v, of the
  ++ domain \spadtype{TwoDimensionalViewport} and returns a list
  ++ containing the draw options from the domain \spadtype{DrawOption}
  ++ for v.
options        : ($,L DROP)                         -> $
  ++ options(v,lopt) takes the given two-dimensional viewport, v,
  ++ of the domain \spadtype{TwoDimensionalViewport} and returns
  ++ v with it's draw options modified to be those which are indicated
  ++ in the given list, \spad{lopt} of domain \spadtype{DrawOption}.
makeViewport2D : (G,L DROP)                         -> $
  ++ makeViewport2D(gi,lopt) creates and displays a viewport window
  ++ of the domain \spadtype{TwoDimensionalViewport} whose graph
  ++ field is assigned to be the given graph, \spad{gi}, of domain
  ++ \spadtype{GraphImage}, and whose options field is set to be
  ++ the list of options, \spad{lopt} of domain \spadtype{DrawOption}.
graphState     : ($,PI,SF,SF,SF,SF,I,I,I,I,PAL,I,PAL,I) -> Void
  ++ graphState(v,num,sX,sY,dX,dY,pts,lns,box,axes,axesC,un,unC,cP)
  ++ sets the state of the characteristics for the graph indicated
  ++ by \spad{num} in the given two-dimensional viewport v, of domain
  ++ \spadtype{TwoDimensionalViewport}, to the values given as
  ++ parameters.  The scaling of the graph in the x and y component
  ++ directions is set to be \spad{sX} and \spad{sY}; the window
  ++ translation in the x and y component directions is set to be
  ++ \spad{dX} and \spad{dY}; The graph points, lines, bounding box,
  ++ axes, or units will be shown in the viewport if their given
  ++ parameters \spad{pts}, \spad{lns}, \spad{box}, \spad{axes} or
  ++ \spad{un} are set to be \spad{1}, but will not be shown if they
  ++ are set to \spad{0}.  The color of the axes and the color of the
  ++ units are indicated by the palette colors \spad{axesC} and
  ++ \spad{unC} respectively.  To display the control panel when
  ++ the viewport window is displayed, set \spad{cP} to \spad{1},
  ++ otherwise set it to \spad{0}.
graphStates    : $                                  -> V GS
  ++ graphStates(v) returns and shows a listing of a record containing
  ++ the current state of the characteristics of each of the ten graph
  ++ records in the given two-dimensional viewport, v, which is of
  ++ domain \spadtype{TwoDimensionalViewport}.
graphs         : $                                  -> V GU
  ++ graphs(v) returns a vector, or list, which is a union of all
  ++ the graphs, of the domain \spadtype{GraphImage}, which are
  ++ allocated for the two-dimensional viewport, v, of domain
```

```
  ++ \spadtype{TwoDimensionalViewport}.  Those graphs which have
  ++ no data are labeled "undefined", otherwise their contents
  ++ are shown.
title          : ($,STR)                              -> Void
  ++ title(v,s) changes the title which is shown in the two-dimensional
  ++ viewport window, v of domain \spadtype{TwoDimensionalViewport}.
putGraph       : ($,G,PI)                             -> Void
  ++ putGraph(v,gi,n) sets the graph field indicated by n, of the
  ++ indicated two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, to be the graph, \spad{gi}
  ++ of domain \spadtype{GraphImage}.  The contents of viewport, v,
  ++ will contain \spad{gi} when the function \spadfun{makeViewport2D}
  ++ is called to create the an updated viewport v.
getGraph       : ($,PI)                               -> G
  ++ getGraph(v,n) returns the graph which is of the domain
  ++ \spadtype{GraphImage} which is located in graph field n
  ++ of the given two-dimensional viewport, v, which is of the
  ++ domain \spadtype{TwoDimensionalViewport}.
axes           : ($,PI,STR)                           -> Void
  ++ axes(v,n,s) displays the axes of the graph in field n of
  ++ the given two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
  ++ not display the axes if s is "off".
axes           : ($,PI,PAL)                           -> Void
  ++ axes(v,n,c) displays the axes of the graph in field n of
  ++ the given two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, with the axes color set to
  ++ the given palette color c.
units          : ($,PI,STR)                           -> Void
  ++ units(v,n,s) displays the units of the graph in field n of
  ++ the given two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
  ++ not display the units if s is "off".
units          : ($,PI,PAL)                           -> Void
  ++ units(v,n,c) displays the units of the graph in field n of
  ++ the given two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, with the units color set to
  ++ the given palette color c.
points         : ($,PI,STR)                           -> Void
  ++ points(v,n,s) displays the points of the graph in field n of
  ++ the given two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
  ++ not display the points if s is "off".
region         : ($,PI,STR)                           -> Void
  ++ region(v,n,s) displays the bounding box of the graph in
  ++ field n of the given two-dimensional viewport, v, which is
  ++ of domain \spadtype{TwoDimensionalViewport}, if s is "on",
  ++ or does not display the bounding box if s is "off".
connect        : ($,PI,STR)                           -> Void
  ++ connect(v,n,s) displays the lines connecting the graph
```

```
  ++ points in field n of the given two-dimensional viewport, v,
  ++ which is of domain \spadtype{TwoDimensionalViewport}, if s
  ++ is "on", or does not display the lines if s is "off".
controlPanel   : ($,STR)                              -> Void
  ++ controlPanel(v,s) displays the control panel of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, if s is "on", or hides
  ++ the control panel if s is "off".
close          : $                                    -> Void
  ++ close(v) closes the viewport window of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, and terminates the
  ++ corresponding process ID.
dimensions     : ($,NNI,NNI,PI,PI)                    -> Void
  ++ dimensions(v,x,y,width,height) sets the position of the
  ++ upper left-hand corner of the two-dimensional viewport, v,
  ++ which is of domain \spadtype{TwoDimensionalViewport}, to
  ++ the window coordinate x, y, and sets the dimensions of the
  ++ window to that of \spad{width}, \spad{height}.  The new
  ++ dimensions are not displayed until the function
  ++ \spadfun{makeViewport2D} is executed again for v.
scale          : ($,PI,F,F)                           -> Void
  ++ scale(v,n,sx,sy) displays the graph in field n of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, scaled by the factor \spad{sx}
  ++ in the x-coordinate direction and by the factor \spad{sy} in
  ++ the y-coordinate direction.
translate      : ($,PI,F,F)                           -> Void
  ++ translate(v,n,dx,dy) displays the graph in field n of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, translated by \spad{dx} in
  ++ the x-coordinate direction from the center of the viewport, and
  ++ by \spad{dy} in the y-coordinate direction from the center.
  ++ Setting \spad{dx} and \spad{dy} to \spad{0} places the center
  ++ of the graph at the center of the viewport.
show           : ($,PI,STR)                           -> Void
  ++ show(v,n,s) displays the graph in field n of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, if s is "on", or does not
  ++ display the graph if s is "off".
move           : ($,NNI,NNI)                          -> Void
  ++ move(v,x,y) displays the two-dimensional viewport, v, which
  ++ is of domain \spadtype{TwoDimensionalViewport}, with the upper
  ++ left-hand corner of the viewport window at the screen
  ++ coordinate position x, y.
update         :($,G,PI)                             -> Void
  ++ update(v,gr,n) drops the graph \spad{gr} in slot \spad{n}
  ++ of viewport \spad{v}. The graph gr must have been
  ++ transmitted already and acquired an integer key.
resize         : ($,PI,PI)                            -> Void
```

```
    ++ resize(v,w,h) displays the two-dimensional viewport, v, which
    ++ is of domain \spadtype{TwoDimensionalViewport}, with a width
    ++ of w and a height of h, keeping the upper left-hand corner
    ++ position unchanged.
  write          : ($,STR)                                -> STR
    ++ write(v,s) takes the given two-dimensional viewport, v, which
    ++ is of domain \spadtype{TwoDimensionalViewport}, and creates
    ++ a directory indicated by s, which contains the graph data
    ++ files for v.
  write          : ($,STR,STR)                            -> STR
    ++ write(v,s,f) takes the given two-dimensional viewport, v, which
    ++ is of domain \spadtype{TwoDimensionalViewport}, and creates
    ++ a directory indicated by s, which contains the graph data
    ++ files for v and an optional file type f.
  write          : ($,STR,L STR)                          -> STR
    ++ write(v,s,lf) takes the given two-dimensional viewport, v, which
    ++ is of domain \spadtype{TwoDimensionalViewport}, and creates
    ++ a directory indicated by s, which contains the graph data
    ++ files for v and the optional file types indicated by the list lf.
  reset          :  $                                     -> Void
    ++ reset(v) sets the current state of the graph characteristics
    ++ of the given two-dimensional viewport, v, which is of domain
    ++ \spadtype{TwoDimensionalViewport}, back to their initial settings.
  key            :  $                                     -> I
    ++ key(v) returns the process ID number of the given two-dimensional
    ++ viewport, v, which is of domain \spadtype{TwoDimensionalViewport}.
  coerce         :  $                                     -> E
    ++ coerce(v) returns the given two-dimensional viewport, v, which
    ++ is of domain \spadtype{TwoDimensionalViewport} as output of
    ++ the domain \spadtype{OutputForm}.

UnivariateLaurentSeries examples
====================================================================

UnivariateLaurentSeries is a domain representing Laurent series in one
variable with coefficients in an arbitrary ring.  The parameters of the
type specify the coefficient ring, the power series variable, and the
center of the power series expansion.  For example,
UnivariateLaurentSeries(Integer,x,3) represents Laurent series in
(x - 3) with integer coefficients.

++ Author: Clifton J. Williamson
++ Date Created: 18 January 1990
++ Date Last Updated: 21 September 1993
++ Description:
++ Dense Laurent series in one variable
++ \spadtype{UnivariateLaurentSeries} is a domain representing Laurent
++ series in one variable with coefficients in an arbitrary ring.  The
++ parameters of the type specify the coefficient ring, the power series
++ variable, and the center of the power series expansion.  For example,
++ \spad{UnivariateLaurentSeries(Integer,x,3)} represents Laurent series in
++ \spad{(x - 3)} with integer coefficients.

UnivariateLaurentSeries(Coef,var,cen): Exports == Implementation where
  Coef : Ring
  var  : Symbol
  cen  : Coef
  I   ==> Integer
  UTS ==> UnivariateTaylorSeries(Coef,var,cen)

  Exports ==> UnivariateLaurentSeriesConstructorCategory(Coef,UTS) with
    coerce: Variable(var) -> %
      ++ \spad{coerce(var)} converts the series variable \spad{var} into a
      ++ Laurent series.
    differentiate: (%,Variable(var)) -> %
      ++ \spad{differentiate(f(x),x)} returns the derivative of
      ++ \spad{f(x)} with respect to \spad{x}.
    if Coef has Algebra Fraction Integer then
      integrate: (%,Variable(var)) -> %
        ++ \spad{integrate(f(x))} returns an anti-derivative of the power
        ++ series \spad{f(x)} with constant coefficient 0.
        ++ We may integrate a series when we can divide coefficients
        ++ by integers.

  Implementation ==> UnivariateLaurentSeriesConstructor(Coef,UTS) add

    variable x == var
    center   x == cen

    coerce(v:Variable(var)) ==
      zero? cen => monomial(1,1)
      monomial(1,1) + monomial(cen,0)

    differentiate(x:%,v:Variable(var)) == differentiate x

    if Coef has Algebra Fraction Integer then
      integrate(x:%,v:Variable(var)) == integrate x

```
=====================================================================
UnivariatePolynomial examples
```

```
================================================================
```

The domain constructor UnivariatePolynomial (abbreviated UP) creates domains of univariate polynomials in a specified variable. For example, the domain UP(a1,POLY FRAC INT) provides polynomials in the single variable a1 whose coefficients are general polynomials with rational number coefficients.

Restriction: Axiom does not allow you to create types where UnivariatePolynomial is contained in the coefficient type of Polynomial. Therefore, UP(x,POLY INT) is legal but POLY UP(x,INT) is not.

UP(x,INT) is the domain of polynomials in the single variable x with integer coefficients.

```
  (p,q) : UP(x,INT)
                          Type: Void

  p := (3*x-1)**2 * (2*x + 8)
       3      2
    18x  + 60x  - 46x + 8
                          Type: UnivariatePolynomial(x,Integer)

  q := (1 - 6*x + 9*x**2)**2
       4       3      2
    81x  - 108x  + 54x  - 12x + 1
                          Type: UnivariatePolynomial(x,Integer)
```

The usual arithmetic operations are available for univariate polynomials.

```
  p**2 + p*q
         7        6        5         4        3        2
    1458x  + 3240x  - 7074x  + 10584x  - 9282x  + 4120x  - 878x + 72
                          Type: UnivariatePolynomial(x,Integer)
```

The operation leadingCoefficient extracts the coefficient of the term of highest degree.

```
  leadingCoefficient p
    18
                          Type: PositiveInteger
```

The operation degree returns the degree of the polynomial. Since the polynomial has only one variable, the variable is not supplied to operations like degree.

```
  degree p
    3
                          Type: PositiveInteger
```

The reductum of the polynomial, the polynomial obtained by subtracting the term of highest order, is returned by reductum.

```
  reductum p
       2
    60x  - 46x + 8
                          Type: UnivariatePolynomial(x,Integer)
```

The operation gcd computes the greatest common divisor of two polynomials.

```
  gcd(p,q)
      2
    9x  - 6x + 1
                          Type: UnivariatePolynomial(x,Integer)
```

The operation lcm computes the least common multiple.

```
  lcm(p,q)
        5       4       3       2
    162x  + 432x  - 756x  + 408x  - 94x + 8
                          Type: UnivariatePolynomial(x,Integer)
```

The operation resultant computes the resultant of two univariate polynomials. In the case of p and q, the resultant is 0 because they share a common root.

```
  resultant(p,q)
    0
                          Type: NonNegativeInteger
```

To compute the derivative of a univariate polynomial with respect to its variable, use the function D.

```
  D p
       2
    54x  + 120x - 46
                          Type: UnivariatePolynomial(x,Integer)
```

Univariate polynomials can also be used as if they were functions. To evaluate a univariate polynomial at some point, apply the polynomial to the point.

```
  p(2)
    300
                          Type: PositiveInteger
```

The same syntax is used for composing two univariate polynomials, i.e. substituting one polynomial for the variable in another. This substitutes q for the variable in p.

```
  p(q)
            12            11            10            9            8
    9565938x   - 38263752x   + 70150212x   - 77944680x  + 58852170x
   +
               7            6           5           4          3         2
    - 32227632x  + 13349448x  - 4280688x  + 1058184x  - 192672x  + 23328x
   +
    - 1536x + 40
                          Type: UnivariatePolynomial(x,Integer)
```

This substitutes p for the variable in q.

```
  q(p)
            12             11             10             9              8
    8503056x   + 113374080x   + 479950272x   + 404997408x  - 1369516896x
   +
                7              6              5              4             3
    - 626146848x  + 2939858712x  - 2780728704x  + 1364312160x  - 396838872x
   +
              2
    69205896x  - 6716184x + 279841
                          Type: UnivariatePolynomial(x,Integer)
```

To obtain a list of coefficients of the polynomial, use coefficients.

```
  l := coefficients p
    [18,60,- 46,8]
                          Type: List Integer
```

From this you can use gcd and reduce to compute the content of the polynomial.

```
  reduce(gcd,l)
    2
                          Type: PositiveInteger
```

Alternatively (and more easily), you can just call content.

```
  content p
    2
                          Type: PositiveInteger
```

Note that the operation coefficients omits the zero coefficients from the list. Sometimes it is useful to convert a univariate polynomial to a vector whose i-th position contains the degree i-1 coefficient of the polynomial.

```
  ux := (x**4+2*x+3)::UP(x,INT)
     4
    x  + 2x + 3
```

```
                          Type: UnivariatePolynomial(x,Integer)
```

To get a complete vector of coefficients, use the operation vectorise, which takes a univariate polynomial and an integer denoting the length of the desired vector.

```
  vectorise(ux,5)
    [3,2,0,0,1]
                          Type: Vector Integer
```

It is common to want to do something to every term of a polynomial, creating a new polynomial in the process.

This is a function for iterating across the terms of a polynomial, squaring each term.

```
  squareTerms(p) ==   reduce(+,[t**2 for t in monomials p])
                          Type: Void
```

Recall what p looked like.

```
  p
       3      2
    18x  + 60x  - 46x + 8
                          Type: UnivariatePolynomial(x,Integer)
```

We can demonstrate squareTerms on p.

```
  squareTerms p
        6        4        2
    324x  + 3600x  + 2116x  + 64
                          Type: UnivariatePolynomial(x,Integer)
```

When the coefficients of the univariate polynomial belong to a field, it is possible to compute quotients and remainders. For example, when the coefficients are rational numbers, as opposed to integers. The important property of a field is that non-zero elements can be divided and produce another element. The quotient of the integers 2 and 3 is not another integer.

```
  (r,s) : UP(a1,FRAC INT)
                          Type: Void

  r := a1**2 - 2/3
      2   2
    a1  - -
          3
                          Type: UnivariatePolynomial(a1,Fraction Integer)

  s := a1 + 4
```

```
    a1 + 4
                          Type: UnivariatePolynomial(a1,Fraction Integer)
```

When the coefficients are rational numbers or rational expressions, the operation quo computes the quotient of two polynomials.

```
  r quo s
    a1 - 4
                          Type: UnivariatePolynomial(a1,Fraction Integer)
```

The operation rem computes the remainder.

```
  r rem s
    46
    --
     3
                          Type: UnivariatePolynomial(a1,Fraction Integer)
```

The operation divide can be used to return a record of both components.

```
  d := divide(r, s)
                                 46
    [quotient= a1 - 4,remainder= --]
                                  3
       Type: Record(quotient: UnivariatePolynomial(a1,Fraction Integer),
                    remainder: UnivariatePolynomial(a1,Fraction Integer))
```

Now we check the arithmetic!

```
  r - (d.quotient * s + d.remainder)
    0
                          Type: UnivariatePolynomial(a1,Fraction Integer)
```

It is also possible to integrate univariate polynomials when the coefficients belong to a field.

```
  integrate r
    1   3   2
    - a1  - - a1
    3       3
                          Type: UnivariatePolynomial(a1,Fraction Integer)

  integrate s
    1   2
    - a1  + 4a1
    2
                          Type: UnivariatePolynomial(a1,Fraction Integer)
```

One application of univariate polynomials is to see expressions in terms of a specific variable.

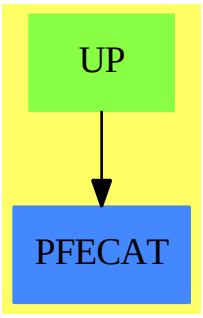
We start with a polynomial in a1 whose coefficients are quotients of polynomials in b1 and b2.

```
t : UP(a1,FRAC POLY INT)
                        Type: Void
```

Since in this case we are not talking about using multivariate polynomials in only two variables, we use Polynomial. We also use Fraction because we want fractions.

```
t := a1**2 - a1/b2 + (b1**2-b1)/(b2+3)
                    2
     2    1      b1  - b1
   a1  - -- a1 + --------
         b2       b2 + 3
                  Type: UnivariatePolynomial(a1,Fraction Polynomial Integer)
```

We push all the variables into a single quotient of polynomials.



```
u : FRAC POLY INT := t
      2  2      2           2
    a1 b2  + (b1  - b1 + 3a1  - a1)b2 - 3a1
    ---------------------------------------
                    2
                   b2  + 3b2
                         Type: Fraction Polynomial Integer
```

Alternatively, we can view this as a polynomial in the variable This is a mode-directed conversion: you indicate as much of the structure as you care about and let Axiom decide on the full type and how to do the transformation.

```
u :: UP(b1,?)
                                 2
       1     2      1        a1 b2 - a1
    ------ b1  - ------ b1 + ----------
    b2 + 3       b2 + 3          b2
                  Type: UnivariatePolynomial(b1,Fraction Polynomial Integer)
```

— **domain UP UnivariatePolynomial** —

```
)abbrev domain UP UnivariatePolynomial
++ Author: Mark Botch
++ Description:
++ This domain represents univariate polynomials in some symbol
++ over arbitrary (not necessarily commutative) coefficient rings.
++ The representation is sparse
++ in the sense that only non-zero terms are represented.
++ Note that if the coefficient ring is a field, then this domain
++ forms a euclidean domain.

UnivariatePolynomial(x:Symbol, R:Ring):
  UnivariatePolynomialCategory(R) with

==========================================================================
UnivariatePuiseuxSeries examples
==========================================================================

UnivariatePuiseuxSeries is a domain representing Puiseux series in one
variable with coefficients in an arbitrary ring.  The parameters of the
type specify the coefficient ring, the power series variable, and the
center of the power series expansion.  For example,
UnivariatePuiseuxSeries(Integer,x,3) represents Puiseux series in
(x - 3) with Integer coefficients.

UnivariatePuiseuxSeriesConstructor examples
=======================================================================

This package enables one to construct a univariate Puiseux series
domain from a univariate Laurent series domain. Univariate
Puiseux series are represented by a pair [r,f(x)], where r is
a positive rational number and f(x) is a Laurent series.
This pair represents the Puiseux series f(x^r).

=====================================================================
UnivariatePuiseuxSeriesWithExponentialSingularity examples
=====================================================================

UnivariatePuiseuxSeriesWithExponentialSingularity is a domain used to
represent functions with essential singularities.  Objects in this
domain are sums, where each term in the sum is a univariate Puiseux
series times the exponential of a univariate Puiseux series.  Thus,
the elements of this domain are sums of expressions of the form
g(x) * exp(f(x)), where g(x) is a univariate Puiseux series and f(x)
is a univariate Puiseux series with no terms of non-negative degree.

====================================================================
UnivariateSkewPolynomial examples
```

```
==========================================================================

Skew or Ore polynomial rings provide a unified framework to
compute with differential and difference equations.

In the following, let A be an integral domain, equipped with two
endomorphisms \sigma and \delta where:

 \sigma: A -> A is an injective ring endomorphism
 \delta: A -> A, the pseudo-derivation with respect to \sigma,
         is an additive endomorphism with

     \delta(ab) = \sigma(a)\delta(b) + \delta(a)b

         for all a,b in A

Note that in the domains and categories below, these properties are
not checked.

The skew polynomial ring [\Delta;\sigma,\delta] is the ring of
polynomials in \Delta with coefficients in A, with the usual addition,
while the product is given by

 \Delta a = \sigma(a)\Delta + \delta(a) for a in A

The two most important examples of skew polynomial rings are:

  K(x)[D,1,\delta], where 1 is the identity on K and \delta is
                    the usual derviative, is the ring of differential
                    polynomials

  K [E,n,\mapsto n+1,0] is the ring of linear recurrence operators
   n                    with polynomial coefficients

--------------------------------------------------------------------------

For example,

The UnivariateSkewPolynomialCategory (OREPCAT) provides a unified
framework for polynomial rings in a non-central indeterminate over
some coefficient ring R. The commutation relations between the
indeterminate x and the coefficient t is given by

   x r = \sigma(r) x + \delta(r)

where \sigma is a ring endomorphism of R
and   \delta is a \sigma-derivation of R
which is an additive map from R to R such that
```

```
   \delta(rs) = \sigma(r) \delta(s) + \delta(r) s

In case \sigma is the identity map on R, a \sigma-derivation of R
is just called a derivation. Here are some examples

We start with a linear ordinary differential operator. First, we
define the coefficient ring to be expressions in one variable x
with fractional coefficients:

   F:=EXPR(FRAC(INT))

Define Dx to be a derivative d/dx:

   Dx:F->F:=f+->D(f,['x])

Define a skew polynomial ring over F with identity endomorphism as
\sigma and derivation d/dx as \delta:

   D0:=OREUP('d,F,1,Dx)

   u:D0:=(operator 'u)(x)

   d:D0:='d

   a:D0:=u^3*d^3+u^2*d^2+u*d+1

            3 3       2 2
        u(x) d  + u(x) d  + u(x)d + 1

   b:D0:=(u+1)*d^2+2*d

                  2
        (u(x) + 1)d  + 2d

   r:=rightDivide(a,b)

                                    3 ,          3       2
                   3      - u(x) u (x) - u(x)  + u(x)
               u(x)
   [quotient= -------- d + ----------------------------,
              u(x) + 1                2
                                    u(x)  + 2u(x) + 1
                    3 ,           3
               2u(x) u (x) + 3u(x)  + u(x)

    remainder= -------------------------- d + 1]
                          2
                   u(x)  + 2u(x) + 1
```

```
r.quotient
```

```
                          3 ,          3       2
           3      - u(x) u (x) - u(x)  + u(x)
        u(x)
      -------- d + ----------------------------
      u(x) + 1               2
                        u(x)  + 2u(x) + 1
```

```
r.remainder
```

```
           3 ,           3
       2u(x) u (x) + 3u(x)  + u(x)

       -------------------------- d + 1
                2
            u(x)  + 2u(x) + 1
```

```
)clear all
```

As a second example, we consider the so-called Weyl algebra.

Define the coefficient ring to be an ordinary polynomial over integers in one variable t

```
R:=UP('t,INT)
```

Define a skew polynomial ring over R with identity map as \sigma and derivation d/dt as \delta. The resulting algebra is then called a Weyl algebra. This is a simple ring over a division ring that is non-commutative, similar to the ring of matrices.

```
W:=OREUP('x,R,1,D)

t:W:='t

x:W:='x
```

Let

```
a:W:=(t-1)*x^4+(t^3+3*t+1)*x^2+2*t*x+t^3
```

```
               4     3           2           3
        (t - 1)x  + (t  + 3t + 1)x  + 2t x + t
```

```
b:W:=(6*t^4+2*t^2)*x^3+3*t^2*x^2
```

```
          4     2  3     2 2
       (6t  + 2t )x  + 3t x
```

Then

```
   a*b
          5     4     3     2  7       4      3      2        6
       (6t  - 6t  + 2t  - 2t )x  + (96t  - 93t  + 13t  - 16t)x
     +
          7      5     4       3       2       5
       (6t  + 20t  + 6t  + 438t  - 406t  - 24)x
     +
           6      5       4      3       2              4
       (48t  + 15t  + 152t  + 61t  + 603t  - 532t - 36)x
     +
          7      5      4       3       2               3
       (6t  + 74t  + 60t  + 226t  + 116t  + 168t - 140)x
     +
          5     3      2            2
       (3t  + 6t  + 12t  + 18t + 6)x

   a^3
         3     2           12      5     4      3      2           10
       (t  - 3t  + 3t - 1)x   + (3t  - 6t  + 12t  - 15t  + 3t + 3)x
     +
          3      2       9      7     6      5      4      3     2            8
       (6t  - 12t  + 6t)x  + (3t  - 3t  + 21t  - 18t  + 24t  - 9t  - 15t - 3)x
     +
          5      4      3      2        7
       (12t  - 12t  + 36t  - 24t  - 12t)x
     +
         9      7     6      5     4      3      2           6
       (t  + 15t  - 3t  + 45t  + 6t  + 36t  + 15t  + 9t + 1)x
     +
          7      5      3      2       5
       (6t  + 48t  + 54t  + 36t  + 6t)x
     +
          9      7     6      5      4      3      2  4
       (3t  + 21t  + 3t  + 39t  + 18t  + 39t  + 12t )x
     +
          7      5      4     3  3      9     7     6      5  2     7     9
       (12t  + 36t  + 12t  + 8t )x  + (3t  + 9t  + 3t  + 12t )x  + 6t x + t
```

```
   )clear all
```

As a third example, we construct a difference operator algebra over

```
the ring of EXPR(INT) by using an automorphism S defined by a
"shift" operation S:EXPR(INT) -> EXPR(INT)

   s(e)(n) = e(n+1)

and an S-derivation defined by DF:EXPR(INT) -> EXPR(INT) as

   DF(e)(n) = e(n+1)-e(n)

Define S to be a "shift" operator, which acts on expressions with
the discrete variable n:

   S:EXPR(INT)->EXPR(INT):=e+->eval(e,[n],[n+1])

Define DF to be a "difference" operator, which acts on expressions
with a discrete variable n:

   DF:EXPR(INT)->EXPR(INT):=e+->eval(e,[n],[n+1])-e

Then define the difference operator algebra D0:

   D0:=OREUP('D,EXPR(INT),morphism S,DF)

   u:=(operator 'u)[n]

   L:D0:='D+u

        D + u(n)

   L^2

         2               2
        D  + 2u(n)D + u(n)

------------------------------------------------------------------------

   )clear all

As a fourth example, we construct a skew polynomial ring by using an
inner derivation \delta induced by a fixed y in R:

   \delta(r) = yr - ry

First we should expose the constructor SquareMatrix so it is visible
in the interpreter:

   )set expose add constructor SquareMatrix

Define R to be the square matrix with integer entries:
```

```
   R:=SQMATRIX(2,INT)

   y:R:=matrix [[1,1],[0,1]]
        +1  1+
        |    |
        +0  1+

Define the inner derivative \delta:

   delta:R->R:=r+->y*r-r*y

Define S to be a skew polynomial determined by \sigma = 1
and \delta as an inner derivative:

   S:=OREUP('x,R,1,delta)

   x:S:='x

   a:S:=matrix [[2,3],[1,1]]
        +2  3+
        |    |
        +1  1+

   x^2*a
        +2  3+ 2   +2  - 2+    +0  - 2+
        |    |x  + |      |x + |      |
        +1  1+     +0  - 2+    +0   0 +

UnivariateTaylorSeries examples
=====================================================================

Dense Taylor series in one variable. UnivariateTaylorSeries is a domain
representing Taylor series in one variable with coefficients in an
arbitrary ring.  The parameters of the type specify the coefficient
ring, the power series variable, and the center of the power series
expansion.  For example, UnivariateTaylorSeries(Integer,x,3) represents
Taylor series in (x - 3) with Integer coefficients.

++ Author: Gaetan Hache
++ Date Created: September 1996
++ Date Last Updated: April, 2010, by Tim Daly
++ Description:
++ Part of the Package for Algebraic Function Fields in one variable PAFF

UnivariateTaylorSeriesCZero(Coef,var): Exports == Implementation where
  Coef :  Ring
  var  :  Symbol
  I    ==> Integer
  NNI  ==> NonNegativeInteger
  P    ==> Polynomial Coef
  RN   ==> Fraction Integer
  ST   ==> Stream
  STT  ==> StreamTaylorSeriesOperations Coef
  TERM ==> Record(k:NNI,c:Coef)
  UP   ==> UnivariatePolynomial(var,Coef)
  Exports ==> UnivariateTaylorSeriesCategory(Coef) with
    coerce: UP -> %
```

```
  ++\spad{coerce(p)} converts a univariate polynomial p in the variable
  ++\spad{var} to a univariate Taylor series in \spad{var}.
univariatePolynomial: (%,NNI) -> UP
  ++\spad{univariatePolynomial(f,k)} returns a univariate polynomial
  ++ consisting of the sum of all terms of f of degree \spad{<= k}.
coerce: Variable(var) -> %
  ++\spad{coerce(var)} converts the series variable \spad{var} into a
  ++ Taylor series.
differentiate: (%,Variable(var)) -> %
  ++ \spad{differentiate(f(x),x)} computes the derivative of
  ++ \spad{f(x)} with respect to \spad{x}.
lagrange: % -> %
  ++\spad{lagrange(g(x))} produces the Taylor series for \spad{f(x)}
  ++ where \spad{f(x)} is implicitly defined as \spad{f(x) = x*g(f(x))}.
lambert: % -> %
  ++\spad{lambert(f(x))} returns \spad{f(x) + f(x^2) + f(x^3) + ...}.
  ++ This function is used for computing infinite products.
  ++ \spad{f(x)} should have zero constant coefficient.
  ++ If \spad{f(x)} is a Taylor series with constant term 1, then
  ++ \spad{product(n = 1..infinity,f(x^n)) = exp(log(lambert(f(x))))}.
oddlambert: % -> %
  ++\spad{oddlambert(f(x))} returns \spad{f(x) + f(x^3) + f(x^5) + ...}.
  ++ \spad{f(x)} should have a zero constant coefficient.
  ++ This function is used for computing infinite products.
  ++ If \spad{f(x)} is a Taylor series with constant term 1, then
  ++ \spad{product(n=1..infinity,f(x^(2*n-1)))=exp(log(oddlambert(f(x))))}.
evenlambert: % -> %
  ++\spad{evenlambert(f(x))} returns \spad{f(x^2) + f(x^4) + f(x^6) + ...}.
  ++ \spad{f(x)} should have a zero constant coefficient.
  ++ This function is used for computing infinite products.
  ++ If \spad{f(x)} is a Taylor series with constant term 1, then
  ++ \spad{product(n=1..infinity,f(x^(2*n)))=exp(log(evenlambert(f(x))))}.
generalLambert: (%,I,I) -> %
  ++\spad{generalLambert(f(x),a,d)} returns \spad{f(x^a) + f(x^(a + d)) +
  ++ f(x^(a + 2 d)) + ... }. \spad{f(x)} should have zero constant
  ++ coefficient and \spad{a} and d should be positive.
revert: % -> %
  ++ \spad{revert(f(x))} returns a Taylor series \spad{g(x)} such that
  ++ \spad{f(g(x)) = g(f(x)) = x}. Series \spad{f(x)} should have constant
  ++ coefficient 0 and 1st order coefficient 1.
multisect: (I,I,%) -> %
  ++\spad{multisect(a,b,f(x))} selects the coefficients of
  ++ \spad{x^((a+b)*n+a)}, and changes this monomial to \spad{x^n}.
invmultisect: (I,I,%) -> %
  ++\spad{invmultisect(a,b,f(x))} substitutes \spad{x^((a+b)*n)}
  ++ for \spad{x^n} and multiples by \spad{x^b}.
if Coef has Algebra Fraction Integer then
  integrate: (%,Variable(var)) -> %
    ++ \spad{integrate(f(x),x)} returns an anti-derivative of the power
    ++ series \spad{f(x)} with constant coefficient 0.
```

```
      ++ We may integrate a series when we can divide coefficients
      ++ by integers.

=====================================================================
UniversalSegment examples
=====================================================================

The UniversalSegment domain generalizes Segment by allowing segments
without a "hi" end point.

  pints := 1..
    1..
                                Type: UniversalSegment PositiveInteger

  nevens := (0..) by -2
    0.. by - 2
                                Type: UniversalSegment NonNegativeInteger

Values of type Segment are automatically converted to type
UniversalSegment when appropriate.

  useg: UniversalSegment(Integer) := 3..10
    3..10
                                Type: UniversalSegment Integer

The operation hasHi is used to test whether a segment has a hi end point.

  hasHi pints
    false
                                Type: Boolean
```

```
  hasHi nevens
    false
                                Type: Boolean

  hasHi useg
    true
                                Type: Boolean
```

All operations available on type Segment apply to UniversalSegment, with the proviso that expansions produce streams rather than lists. This is to accommodate infinite expansions.

```
  expand pints
    [1,2,3,4,5,6,7,8,9,10,...]
                                Type: Stream Integer

  expand nevens
    [0,- 2,- 4,- 6,- 8,- 10,- 12,- 14,- 16,- 18,...]
                                Type: Stream Integer

  expand [1, 3, 10..15, 100..]
    [1,3,10,11,12,13,14,15,100,101,...]
                                Type: Stream Integer
```

— domain UNISEG UniversalSegment —

```
)abbrev domain UNISEG UniversalSegment
++ Author:  Robert S. Sutor
++ Date Created: 1987
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides segments which may be half open.
++ That is, ranges of the form \spad{a..} or \spad{a..b}.

UniversalSegment(S: Type): SegmentCategory(S) with
    SEGMENT: S -> %
        ++ \spad{l..} produces a half open segment,
        ++ that is, one with no upper bound.
    segment: S -> %
        ++ segment(l) is an alternate way to construct the segment \spad{l..}.
    coerce : Segment S -> %
        ++ coerce(x) allows \spadtype{Segment} values to be used as %.
    hasHi: % -> Boolean
        ++ hasHi(s) tests whether the segment s has an upper bound.

    if S has SetCategory then SetCategory

    if S has OrderedRing then
      SegmentExpansionCategory(S, Stream S)
--    expand : (List %, S) -> Stream S
```

```
--    expand : (%, S) -> Stream S

```
=====================================================================
Vector examples
=====================================================================

The Vector domain is used for storing data in a one-dimensional
indexed data structure.  A vector is a homogeneous data structure in
that all the components of the vector must belong to the same Axiom
domain.  Each vector has a fixed length specified by the user; vectors
are not extensible.  This domain is similar to the OneDimensionalArray
domain, except that when the components of a Vector belong to a Ring,
arithmetic operations are provided.

As with the OneDimensionalArray domain, a Vector can be created by
calling the operation new, its components can be accessed by calling
the operations elt and qelt, and its components can be reset by
calling the operations setelt and qsetelt.

This creates a vector of integers of length 5 all of whose components are 12.

  u : VECTOR INT := new(5,12)
    [12,12,12,12,12]
                                Type: Vector Integer

This is how you create a vector from a list of its components.
```

```
  v : VECTOR INT := vector([1,2,3,4,5])
    [1,2,3,4,5]
                                Type: Vector Integer
```

Indexing for vectors begins at 1. The last element has index equal to the length of the vector, which is computed by #.

```
 #(v)
    5
                                Type: PositiveInteger
```

This is the standard way to use elt to extract an element. Functionally, it is the same as if you had typed elt(v,2).

```
  v.2
    2
                                Type: PositiveInteger
```

This is the standard way to use setelt to change an element. It is the same as if you had typed setelt(v,3,99).

```
  v.3 := 99
    99
                                Type: PositiveInteger
```

Now look at v to see the change. You can use qelt and qsetelt (instead of elt and setelt, respectively) but only when you know that the index is within the valid range.

```
  v
    [1,2,99,4,5]
                                Type: Vector Integer
```

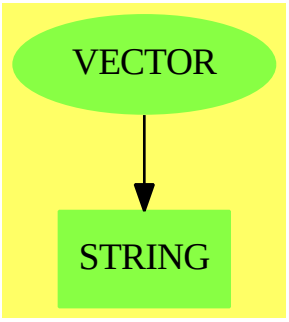
When the components belong to a Ring, Axiom provides arithmetic operations for Vector. These include left and right scalar multiplication.

```
  5 * v
    [5,10,495,20,25]
                                Type: Vector Integer

  v * 7
    [7,14,693,28,35]
                                Type: Vector Integer

  w : VECTOR INT := vector([2,3,4,5,6])
    [2,3,4,5,6]
                                Type: Vector Integer
```

Addition and subtraction are also available.



```
  v + w
    [3,5,103,9,11]
                                  Type: Vector Integer
```

Of course, when adding or subtracting, the two vectors must have the same length or an error message is displayed.

```
  v - w
    [- 1,- 1,95,- 1,- 1]
                                  Type: Vector Integer
```

— Void.help —

```
====================================================================
Void examples
====================================================================

When an expression is not in a value context, it is given type Void.
For example, in the expression

  r := (a; b; if c then d else e; f)

values are used only from the subexpressions c and f: all others are thrown
away.  The subexpressions a, b, d and e are evaluated for side-effects only
and have type Void.  There is a unique value of type Void.

You will most often see results of type Void when you declare a variable.

  a : Integer
                                Type: Void

Usually no output is displayed for Void results.  You can force the
display of a rather ugly object by issuing

  )set message void on

  b : Fraction Integer
                                Type: Void

  )set message void off

All values can be converted to type Void.

  3::Void
                                Type: Void
```

```
Once a value has been converted to Void, it cannot be recovered.

  % :: PositiveInteger
   Cannot convert from type Void to PositiveInteger for value "()"

====================================================================
WuWenTsunTriangularSet examples
====================================================================
```

```
The WuWenTsunTriangularSet domain constructor implements the
characteristic set method of Wu Wen Tsun.  This algorithm computes a
list of triangular sets from a list of polynomials such that the
algebraic variety defined by the given list of polynomials decomposes
into the union of the regular-zero sets of the computed triangular
sets.  The constructor takes four arguments.  The first one, R, is the
coefficient ring of the polynomials; it must belong to the category
IntegralDomain. The second one, E, is the exponent monoid of the
polynomials; it must belong to the category OrderedAbelianMonoidSup.
The third one, V, is the ordered set of variables; it must belong to
the category OrderedSet.  The last one is the polynomial ring; it must
belong to the category RecursivePolynomialCategory(R,E,V).  The
abbreviation for WuWenTsunTriangularSet is WUTSET.

Let us illustrate the facilities by an example.

Define the coefficient ring.

  R := Integer
    Integer
                                Type: Domain

Define the list of variables,

  ls : List Symbol := [x,y,z,t]
    [x,y,z,t]
                                Type: List Symbol

and make it an ordered set;

  V := OVAR(ls)
    OrderedVariableList [x,y,z,t]
                                Type: Domain

then define the exponent monoid.

  E := IndexedExponents V
    IndexedExponents OrderedVariableList [x,y,z,t]
                                Type: Domain

Define the polynomial ring.

  P := NSMP(R, V)
    NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
                                Type: Domain

Let the variables be polynomial.

  x: P := 'x
```

```
   x
      Type: NewSparseMultivariatePolynomial(Integer,
              OrderedVariableList [x,y,z,t])

  y: P := 'y
    y
      Type: NewSparseMultivariatePolynomial(Integer,
              OrderedVariableList [x,y,z,t])

  z: P := 'z
    z
      Type: NewSparseMultivariatePolynomial(Integer,
              OrderedVariableList [x,y,z,t])

  t: P := 't
    t
      Type: NewSparseMultivariatePolynomial(Integer,
              OrderedVariableList [x,y,z,t])
```

Now call the WuWenTsunTriangularSet domain constructor.

```
  T := WUTSET(R,E,V,P)
  WuWenTsunTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t]
  ,OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,Ordere
  dVariableList [x,y,z,t]))
                               Type: Domain
```

Define a polynomial system.

```
  p1 := x ** 31 - x ** 6 - x - y
      31    6
     x   - x  - x - y
              Type: NewSparseMultivariatePolynomial(Integer,
                      OrderedVariableList [x,y,z,t])

  p2 := x ** 8  - z
      8
     x  - z
              Type: NewSparseMultivariatePolynomial(Integer,
                      OrderedVariableList [x,y,z,t])

  p3 := x ** 10 - t
      10
     x   - t
              Type: NewSparseMultivariatePolynomial(Integer,
                      OrderedVariableList [x,y,z,t])

  lp := [p1, p2, p3]
      31    6          8      10
    [x   - x  - x - y,x  - z,x   - t]
```

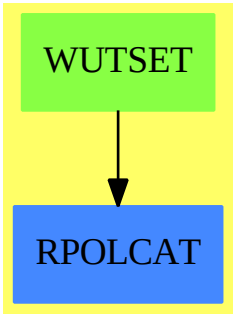
```
        Type: List NewSparseMultivariatePolynomial(Integer,
                    OrderedVariableList [x,y,z,t])
```

Compute a characteristic set of the system.

```
  characteristicSet(lp)$T
     5    4  4 2 2     3 4        7     4      6    6    3      3     3     3
   {z  - t ,t z y  + 2t z y + (- t  + 2t  - t)z  + t z,(t  - 1)z x - z y - t }
           Type: Union(WuWenTsunTriangularSet(Integer,
                         IndexedExponents OrderedVariableList [x,y,z,t],
                         OrderedVariableList [x,y,z,t],
                         NewSparseMultivariatePolynomial(Integer,
                           OrderedVariableList [x,y,z,t])),...)
```

Solve the system.

```
  zeroSetSplit(lp)$T
               3      5    4  3     3    2
  [{t,z,y,x}, {t  - 1,z  - t ,z y + t ,z x  - t},
     5    4  4 2 2     3 4        7     4      6    6    3      3     3     3
   {z  - t ,t z y  + 2t z y + (- t  + 2t  - t)z  + t z,(t  - 1)z x - z y - t }]
         Type: List WuWenTsunTriangularSet(Integer,
                      IndexedExponents OrderedVariableList [x,y,z,t],
                      OrderedVariableList [x,y,z,t],
                      NewSparseMultivariatePolynomial(Integer,
                         OrderedVariableList [x,y,z,t]))
```



The RegularTriangularSet and SquareFreeRegularTriangularSet domain constructors, the LazardSetSolvingPackage package constructors as well as, SquareFreeRegularTriangularSet and ZeroDimensionalSolvePackage package constructors also provide operations to compute triangular decompositions of algebraic varieties. These five constructor use a special kind of characteristic sets, called regular triangular sets. These special characteristic sets have better properties than the general ones. Regular triangular sets and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The decomposition algorithm (due to the third author) available in the four above constructors provide generally better timings than the characteristic set method. In fact, the WUTSET constructor remains interesting for the purpose of manipulating characteristic sets whereas the other constructors are more convenient for solving polynomial systems.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

```
++ Author: Marc Moreno Maza (marc@nag.co.uk)
++ Date Created: 11/18/1995
++ Date Last Updated: 12/15/1998
++ References :
++ [1] W. T. WU "A Zero Structure Theorem for polynomial equations solving"
++      MM Research Preprints, 1987.
++ [2] D. M. WANG "An implementation of the characteristic set method in Maple"
++      Proc. DISCO'92. Bath, England.
++ Description:
++ A domain constructor of the category \axiomType{GeneralTriangularSet}.
++ The only requirement for a list of polynomials to be a member of such
++ a domain is the following: no polynomial is constant and two distinct
++ polynomials have distinct main variables. Such a triangular set may
++ not be auto-reduced or consistent. The construct operation
++ does not check the previous requirement. Triangular sets are stored
++ as sorted lists w.r.t. the main variables of their members.
++ Furthermore, this domain exports operations dealing with the
++ characteristic set method of Wu Wen Tsun and some optimizations
++ mainly proposed by Dong Ming Wang.

  Exports ==  TriangularSetCategory(R,E,V,P) with

     medialSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
        ++ \axiom{medialSet(ps,redOp?,redOp)} returns \axiom{bs} a basic set
        ++ (in Wu Wen Tsun sense w.r.t the reduction-test \axiom{redOp?})
        ++ of some set generating the same ideal as \axiom{ps} (with
        ++ rank not higher than  any basic set of \axiom{ps}), if no non-zero
        ++ constant polynomials appear during the computatioms, else
        ++ \axiom{"failed"} is returned. In the former case, \axiom{bs} has to be
```

```
      ++ understood as a candidate for being a characteristic set of \axiom{ps}.
      ++ In the original algorithm, \axiom{bs} is simply a basic set of \axiom{ps}.
   medialSet: LP -> Union($,"failed")
      ++ \axiom{medial(ps)} returns the same as
      ++ \axiom{medialSet(ps,initiallyReduced?,initiallyReduce)}.
   characteristicSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
      ++ \axiom{characteristicSet(ps,redOp?,redOp)} returns a non-contradictory
      ++ characteristic set of \axiom{ps} in Wu Wen Tsun sense w.r.t the
      ++ reduction-test \axiom{redOp?} (using \axiom{redOp} to reduce
      ++ polynomials w.r.t a \axiom{redOp?} basic set), if no
      ++ non-zero constant polynomial appear during those reductions,
      ++ else \axiom{"failed"} is returned.
      ++ The operations \axiom{redOp} and \axiom{redOp?} must satisfy
      ++ the following conditions: \axiom{redOp?(redOp(p,q),q)} holds
      ++ for every polynomials \axiom{p,q} and there exists an integer
      ++ \axiom{e} and a polynomial \axiom{f} such that we have
      ++ \axiom{init(q)^e*p = f*q + redOp(p,q)}.
   characteristicSet: LP -> Union($,"failed")
      ++ \axiom{characteristicSet(ps)} returns the same as
      ++ \axiom{characteristicSet(ps,initiallyReduced?,initiallyReduce)}.
   characteristicSerie  : (LP,((P,P)->B),((P,P)->P)) -> List $
      ++ \axiom{characteristicSerie(ps,redOp?,redOp)} returns a list \axiom{lts}
      ++ of triangular sets such that the zero set of \axiom{ps} is the
      ++ union of the regular zero sets of the members of \axiom{lts}.
      ++ This is made by the Ritt and Wu Wen Tsun process applying
      ++ the operation \axiom{characteristicSet(ps,redOp?,redOp)}
      ++ to compute characteristic sets in Wu Wen Tsun sense.
   characteristicSerie: LP ->  List $
      ++ \axiom{characteristicSerie(ps)} returns the same as
      ++ \axiom{characteristicSerie(ps,initiallyReduced?,initiallyReduce)}.

Chapter 25

Chapter X

domain XDPOLY XDistributedPolynomial

Polynomial arithmetic with non-commutative variables has been improved by a contribution of Michel Petitot (University of Lille I, France). The domain constructor **XDistributedPolynomial** provide a distributed representation for these polynomials. It is the non-commutative equivalent for the **DistributedMultivariatePolynomial** constructor.

=====================================================================
XPBWPolynomial examples
=====================================================================

This domain constructor implements polynomials in non-commutative
variables written in the Poincare-Birkhoff-Witt basis from the
Lyndon basis.

These polynomials can be used to compute Baker-Campbell-Hausdorff relations.

```
)abbrev domain XPBWPOLY XPBWPolynomial
++ Author: Michel Petitot (petitot@lifl.fr).
```

```
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Description:
++ This domain constructor implements polynomials in non-commutative
++ variables written in the Poincare-Birkhoff-Witt basis from the
++ Lyndon basis.
++ These polynomials can be used to compute Baker-Campbell-Hausdorff
++ relations.

=====================================================================
XPolynomial examples
=====================================================================

The XPolynomial domain constructor implements multivariate polynomials
whose set of variables is Symbol.  These variables do not commute.
The only parameter of this construtor is the coefficient ring which
may be non-commutative.  However, coefficients and variables commute.
The representation of the polynomials is recursive.  The abbreviation
for XPolynomial is XPOLY.

Other constructors like XPolynomialRing, XRecursivePolynomial as well
as XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement
multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPOLY domain constructor.

Define a polynomial ring over the integers.

  poly := XPolynomial(Integer)
    XPolynomial Integer
                                  Type: Domain
```

Define a first polynomial,

```
  pr: poly := 2*x + 3*y-5
    - 5 + x 2 + y 3
                                  Type: XPolynomial Integer
```

and a second one.

```
  pr2: poly := pr*pr
    25 + x(- 20 + x 4 + y 6) + y(- 30 + x 6 + y 9)
                                  Type: XPolynomial Integer
```

Rewrite pr in a distributive way,

```
  pd  := expand pr
    - 5 + 2x + 3y
                                  Type: XDistributedPolynomial(Symbol,Integer)
```

compute its square,

```
  pd2 := pd*pd
                         2                   2
    25 - 20x - 30y + 4x  + 6x y + 6y x + 9y
                                  Type: XDistributedPolynomial(Symbol,Integer)
```

and checks that:

```
  expand(pr2) - pd2
    0
                                  Type: XDistributedPolynomial(Symbol,Integer)
```

We define:

```
  qr :=  pr**3
     - 125 + x(150 + x(- 60 + x 8 + y 12) + y(- 90 + x 12 + y 18))
   +
     y(225 + x(- 90 + x 12 + y 18) + y(- 135 + x 18 + y 27))
                                  Type: XPolynomial Integer
```

and:

```
  qd :=  pd**3
                              2                         2     3      2
     - 125 + 150x + 225y - 60x  - 90x y - 90y x - 135y  + 8x  + 12x y + 12x y x
   +
          2        2                2       3
     18x y  + 12y x  + 18y x y + 18y x + 27y
                                  Type: XDistributedPolynomial(Symbol,Integer)
```

We truncate qd at degree 3.

```
  trunc(qd,2)
                              2                       2
    - 125 + 150x + 225y - 60x  - 90x y - 90y x - 135y
                                Type: XDistributedPolynomial(Symbol,Integer)
```

The same for qr:

```
  trunc(qr,2)
    - 125 + x(150 + x(- 60) + y(- 90)) + y(225 + x(- 90) + y(- 135))
                                Type: XPolynomial Integer
```

We define:

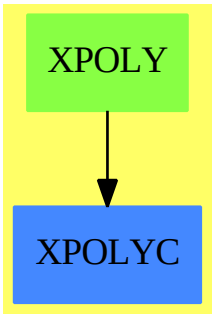
```
  Word := OrderedFreeMonoid Symbol
    OrderedFreeMonoid Symbol
                                Type: Domain
```

and:

```
  w: Word := x*y**2
       2
    x y
                                Type: OrderedFreeMonoid Symbol
```

We can compute the right-quotient of qr by r:

```
  rquo(qr,w)
    18
                                Type: XPolynomial Integer
```



and the shuffle-product of pr by r:

```
  sh(pr,w::poly)
    x(x y y 4 + y(x y 2 + y(- 5 + x 2 + y 9))) + y x y y 3
                                Type: XPolynomial Integer
```

=====================================================================
XPolynomialRing examples
=====================================================================

The XPolynomialRing domain constructor implements generalized
polynomials with coefficients from an arbitrary Ring (not necessarily
commutative) and whose exponents are words from an arbitrary
OrderedMonoid (not necessarily commutative too).  Thus these
polynomials are (finite) linear combinations of words.

This constructor takes two arguments.  The first one is a Ring and the
second is an OrderedMonoid.  The abbreviation for XPolynomialRing is XPR.

Other constructors like XPolynomial, XRecursivePolynomial,
XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement
multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPR domain constructor.

Define the free ordered monoid generated by the symbols.

  Word := OrderedFreeMonoid(Symbol)
    OrderedFreeMonoid Symbol
                                Type: Domain

Define the linear combinations of these words with integer coefficients.

  poly:= XPR(Integer,Word)
    XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
                                Type: Domain

Then we define a first element from poly.

  p:poly := 2 * x - 3 * y + 1
    1 + 2x - 3y
                    Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)

And a second one.

  q:poly := 2 * x + 1
    1 + 2x
```

```
                    Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

We compute their sum,

```
  p + q
    2 + 4x - 3y
                    Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

their product,

```
  p * q
                      2
    1 + 4x - 3y + 4x  - 6y x
                    Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

and see that variables do not commute.

```
  (p+q)**2-p**2-q**2-2*p*q
    - 6x y + 6y x
                    Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

Now we define a ring of square matrices,

```
  M := SquareMatrix(2,Fraction Integer)
    SquareMatrix(2,Fraction Integer)
                                  Type: Domain
```

and the linear combinations of words with these matrices as coefficients.

```
  poly1:= XPR(M,Word)
   XPolynomialRing(SquareMatrix(2,Fraction Integer),OrderedFreeMonoid Symbol)
                                  Type: Domain
```

Define a first matrix,

```
  m1:M := matrix [ [i*j**2 for i in 1..2] for j in 1..2]
         +1  2+
         |    |
         +4  8+
                                  Type: SquareMatrix(2,Fraction Integer)
```

a second one,

```
  m2:M := m1 - 5/4
         +  1    +
         |- -  2 |
         |  4    |
         |       |
         |     27|
         | 4   --|
```

```
        +      4+
                                Type: SquareMatrix(2,Fraction Integer)
```

and a third one.

```
  m3: M := m2**2
        +129     +
        |---  13 |
        | 16     |
        |        |
        |     857|
        |26   ---|
        +      16+
                               Type: SquareMatrix(2,Fraction Integer)
```

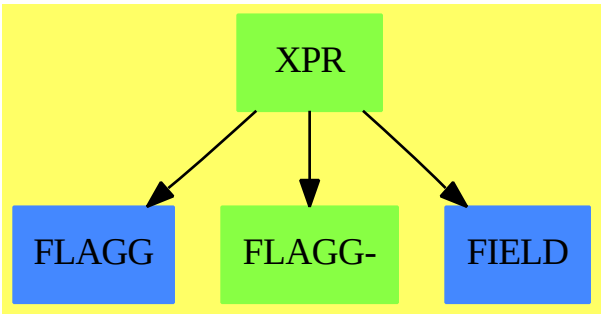
Define a polynomial,

```
  pm:poly1   := m1*x + m2*y + m3*z - 2/3
        +  2     +             +  1    +    +129     +
        |- -   0 |             |- -  2 |    |---  13 |
        |  3     |   +1  2+    |  4    |    | 16     |
        |        | + |    |x + |       |y + |        |z
        |       2|   +4  8+    |     27|    |     857|
        | 0   - -|             | 4   --|    |26   ---|
        +       3+             +      4+    +      16+
     Type: XPolynomialRing(SquareMatrix(2,Fraction Integer),
                           OrderedFreeMonoid Symbol)
```

a second one,

```
  qm:poly1 := pm - m1*x
        +  2     +   +  1    +    +129     +
        |- -   0 |   |- -  2 |    |---  13 |
        |  3     |   |  4    |    | 16     |
        |        | + |       |y + |        |z
        |       2|   |     27|    |     857|
        | 0   - -|   | 4   --|    |26   ---|
        +       3+   +      4+    +      16+
      Type: XPolynomialRing(SquareMatrix(2,Fraction Integer),
                            OrderedFreeMonoid Symbol)
```

and the following power.



```
  qm**3
     +   8      +   +  1  8+    +43   52 +    +  129       +
     |- --   0  |   |- -  -|    |--   -- |    |- ---  - 26 |

)abbrev domain XPR XPolynomialRing
++ Author: Michel Petitot petitot@lifl.fr
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Description:
++ This domain represents generalized polynomials with coefficients
++ (from a not necessarily commutative ring), and words
++ belonging to an arbitrary \spadtype{OrderedMonoid}.
++ This type is used, for instance, by the \spadtype{XDistributedPolynomial}
++ domain constructor where the Monoid is free.

XPolynomialRing(R:Ring,E:OrderedMonoid): T == C where
  TERM   ==> Record(k: E, c: R)
  EX     ==> OutputForm
  NNI    ==> NonNegativeInteger

  T == Join(Ring, XAlgebra(R), FreeModuleCat(R,E)) with
    --operations
      "*": (%,R) -> %
```

```
      ++ \spad{p*r} returns the product of \spad{p} by \spad{r}.
    "#": % -> NonNegativeInteger
      ++ \spad{# p} returns the number of terms in \spad{p}.
    coerce: E -> %
      ++ \spad{coerce(e)} returns \spad{1*e}
    maxdeg: % -> E
      ++ \spad{maxdeg(p)} returns the greatest word occurring in the polynomial \spad{p}
      ++ with a non-zero coefficient. An error is produced if  \spad{p} is zero.
    mindeg: % -> E
      ++ \spad{mindeg(p)} returns the smallest word occurring in the polynomial \spad{p}
      ++ with a non-zero coefficient. An error is produced if  \spad{p} is zero.
    reductum : % -> %
      ++ \spad{reductum(p)} returns \spad{p} minus its leading term.
      ++ An error is produced if  \spad{p} is zero.
    coef  : (%,E) -> R
      ++ \spad{coef(p,e)} extracts the coefficient of the monomial \spad{e}.
      ++ Returns zero if \spad{e} is not present.
    constant?:% -> Boolean
      ++ \spad{constant?(p)} tests whether the polynomial \spad{p} belongs to the
      ++ coefficient ring.
    constant: % -> R
      ++ \spad{constant(p)} return the constant term of \spad{p}.
    quasiRegular? : % -> Boolean

This type supports multivariate polynomials whose variables do not commute.
The representation is recursive. The coefficient ring may be
non-commutative. Coefficients and variables commute.

See Also:
o )show XRecursivePolynomial
```

———-

Polynomial arithmetic with non-commutative variables has been improved by a contribution of Michel Petitot (University of Lille I, France). The domain constructors **XRecursivePolynomial** provides a recursive for these polynomials. It is the non-commutative equivalents for the **SparseMultivariatePolynomial** constructor.

The bootstrap code

BOOLEAN.lsp

BOOLEAN depends on **ORDSET** which depends on **SETCAT** which depends on **BASTYPE** which depends on **BOOLEAN**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated BOOLEAN domain which we can write into the **MID** directory. We compile the lisp code and copy the **BOOLEAN.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

———-

ILIST.lsp BOOTSTRAP

ILIST depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ILIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **ILIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— ILIST.lsp BOOTSTRAP —

INT.lsp BOOTSTRAP

INT depends on **OINTDOM** which depends on **ORDRING** which depends on **INT**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **INT** category which we can write into the **MID** directory. We compile the lisp code and copy the **INT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

———-

ISTRING.lsp BOOTSTRAP

ISTRING depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ISTRING** category which we can write into the **MID** directory. We compile the lisp code and copy the **ISTRING.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— ISTRING.lsp BOOTSTRAP —

LIST.lsp BOOTSTRAP

LIST depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **LIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **LIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— LIST.lsp BOOTSTRAP —

NNI.lsp BOOTSTRAP

NNI depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **NNI** category which we can write into the **MID** directory. We compile the lisp code and copy the **NNI.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

PI.lsp BOOTSTRAP

PI depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **PI** category which we can write into the **MID** directory. We compile the lisp code and copy the **PI.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

REF.lsp BOOTSTRAP

REF depends on a chain of files. We need to break this cycle to build the algebra. So

we keep a cached copy of the translated **REF** category which we can write into the **MID** directory. We compile the lisp code and copy the **REF.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

———-

SYMBOL.lsp BOOTSTRAP

SYMBOL depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **SYMBOL** category which we can write into the **MID** directory. We compile the lisp code and copy the **SYMBOL.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— SYMBOL.lsp BOOTSTRAP —

VECTOR.lsp BOOTSTRAP

VECTOR depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **VECTOR** category which we can write into the **MID** directory. We compile the lisp code and copy the **VECTOR.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.
