BasicOperator (BOP) . . . 273
domain BSD BasicStochasticDifferential . . . 278
BasicStochasticDifferential (BSD) . . . 285
domain BINARY BinaryExpansion . . . 288
BinaryExpansion (BINARY) . . . 292
domain BINFILE BinaryFile . . . 293
BinaryFile (BINFILE) . . . 295
domain BSTREE BinarySearchTree . . . 297
BinarySearchTree (BSTREE) . . . 302
domain BTOURN BinaryTournament . . . 304
BinaryTournament (BTOURN) . . . 306
domain BTREE BinaryTree . . . 308
BinaryTree (BTREE) . . . 310
domain BITS Bits . . . 312
Bits (BITS) . . . 314
domain BLHN BlowUpWithHamburgerNoether . . . 315
BlowUpWithHamburgerNoether (BLHN) . . . 317
domain BLQT BlowUpWithQuadTrans . . . 318
BlowUpWithQuadTrans (BLQT) . . . 319
domain BOOLEAN Boolean . . . 321
Boolean (BOOLEAN) . . . 322

4 Chapter C **325**
domain CARD CardinalNumber . . . 325
CardinalNumber (CARD) . . . 332
domain CARTEN CartesianTensor . . . 336
CartesianTensor (CARTEN) . . . 356
domain CHAR Character . . . 368
Character (CHAR) . . . 373
domain CCLASS CharacterClass . . . 376
CharacterClass (CCLASS) . . . 381
domain CLIF CliffordAlgebra[?, ?] . . . 384
Vector (linear) spaces . . . 384
Quadratic Forms[?] . . . 386
Quadratic spaces, Clifford Maps[?, ?] . . . 386
Universal Clifford algebras[?] . . . 386
Real Clifford algebras $\mathbb{R}_{p,q}$[?] . . . 386
Notation for integer sets . . . 387
Frames for Clifford algebras[?, ?, ?] . . . 387
Real frame groups[?, ?] . . . 387
Canonical products[?, ?, ?] . . . 388
Clifford algebra of frame group[?, ?, ?, ?] . . . 388
Neutral matrix representations[?, ?, ?] . . . 388
CliffordAlgebra (CLIF) . . . 401
domain COLOR Color . . . 406
Color (COLOR) . . . 407
domain COMM Commutator . . . 409
Commutator (COMM) . . . 411
domain COMPLEX Complex . . . 412
Complex (COMPLEX) . . . 418
domain CDFMAT ComplexDoubleFloatMatrix . . . 421
ComplexDoubleFloatMatrix (CDFMAT) . . . 426
domain CDFVEC ComplexDoubleFloatVector . . . 428
ComplexDoubleFloatVector (CDFVEC) . . . 432
domain CONTFRAC ContinuedFraction . . . 434
ContinuedFraction (CONTFRAC) . . . 445

5 Chapter D **453**
domain DBASE Database . . . 453
Database (DBASE) . . . 454
domain DLIST DataList . . . 456
DataList (DLIST) . . . 459
domain DECIMAL DecimalExpansion . . . 461
DecimalExpansion (DECIMAL) . . . 465
Denavit-Hartenberg Matrices . . . 466
Homogeneous Transformations . . . 466
Notation . . . 467
Vectors . . . 468

Planes . . . 469
Transformations . . . 471
Translation Transformation . . . 471
Rotation Transformations . . . 473
Coordinate Frames . . . 476
Relative Transformations . . . 477
Objects . . . 478
Inverse Transformations . . . 478
General Rotation Transformation . . . 479
Equivalent Angle and Axis of Rotation . . . 482
Example 1.1 . . . 485
Stretching and Scaling . . . 486
Perspective Transformations . . . 487
Transform Equations . . . 489
Summary . . . 489
DenavitHartenbergMatrix (DHMATRIX) . . . 491
domain DEQUEUE Dequeue . . . 494
Dequeue (DEQUEUE) . . . 512
domain DERHAM DeRhamComplex . . . 518
DeRhamComplex (DERHAM) . . . 530
domain DSTREE DesingTree . . . 533
DesingTree (DSTREE) . . . 534
domain DSMP DifferentialSparseMultivariatePolynomial . . . 537
DifferentialSparseMultivariatePolynomial (DSMP) . . . 541
domain DIRPROD DirectProduct . . . 543
DirectProduct (DIRPROD) . . . 547
domain DPMM DirectProductMatrixModule . . . 549
DirectProductMatrixModule (DPMM) . . . 552
domain DPMO DirectProductModule . . . 554
DirectProductModule (DPMO) . . . 557
domain DIRRING DirichletRing . . . 558
DirichletRing (DIRRING) . . . 563
domain DMP DistributedMultivariatePolynomial . . . 567
DistributedMultivariatePolynomial (DMP) . . . 571
domain DIV Divisor . . . 573
Divisor (DIV) . . . 575
domain DFLOAT DoubleFloat . . . 578
DoubleFloat (DFLOAT) . . . 586
domain DFMAT DoubleFloatMatrix . . . 595
DoubleFloatMatrix (DFMAT) . . . 599
domain DFVEC DoubleFloatVector . . . 601
DoubleFloatVector (DFVEC) . . . 605
domain DROPT DrawOption . . . 606
DrawOption (DROPT) . . . 608
domain D01AJFA d01ajfAnnaType . . . 613
d01ajfAnnaType (D01AJFA) . . . 614

domain D01AKFA d01akfAnnaType . . . 615
d01akfAnnaType (D01AKFA) . . . 617
domain D01ALFA d01alfAnnaType . . . 618
d01alfAnnaType (D01ALFA) . . . 620
domain D01AMFA d01amfAnnaType . . . 622
d01amfAnnaType (D01AMFA) . . . 623
domain D01ANFA d01anfAnnaType . . . 625
d01anfAnnaType (D01ANFA) . . . 626
domain D01APFA d01apfAnnaType . . . 628
d01apfAnnaType (D01APFA) . . . 629
domain D01AQFA d01aqfAnnaType . . . 631
d01aqfAnnaType (D01AQFA) . . . 633
domain D01ASFA d01asfAnnaType . . . 635
d01asfAnnaType (D01ASFA) . . . 636
domain D01FCFA d01fcfAnnaType . . . 638
d01fcfAnnaType (D01FCFA) . . . 639
domain D01GBFA d01gbfAnnaType . . . 641
d01gbfAnnaType (D01GBFA) . . . 643
domain D01TRNS d01TransformFunctionType . . . 645
d01TransformFunctionType (D01TRNS) . . . 646
domain D02BBFA d02bbfAnnaType . . . 649
d02bbfAnnaType (D02BBFA) . . . 651
domain D02BHFA d02bhfAnnaType . . . 653
d02bhfAnnaType (D02BHFA) . . . 654
domain D02CJFA d02cjfAnnaType . . . 657
d02cjfAnnaType (D02CJFA) . . . 658
domain D02EJFA d02ejfAnnaType . . . 660
d02ejfAnnaType (D02EJFA) . . . 661
domain D03EEFA d03eefAnnaType . . . 664
d03eefAnnaType (D03EEFA) . . . 665
domain D03FAFA d03fafAnnaType . . . 667
d03fafAnnaType (D03FAFA) . . . 668

6 Chapter E **671**
domain EFULS ElementaryFunctionsUnivariateLaurentSeries . . . 671
ElementaryFunctionsUnivariateLaurentSeries (EFULS) . . . 672
domain EFUPXS ElementaryFunctionsUnivariatePuiseuxSeries . . . 680
ElementaryFunctionsUnivariatePuiseuxSeries (EFUPXS) . . . 681
domain EQ Equation . . . 687
Equation (EQ) . . . 691
domain EQTBL EqTable . . . 696
EqTable (EQTBL) . . . 698
domain EMR EuclideanModularRing . . . 699
EuclideanModularRing (EMR) . . . 701
domain EXIT Exit . . . 704
Exit (EXIT) . . . 707

domain EXPEXPAN ExponentialExpansion . . . 708
ExponentialExpansion (EXPEXPAN) . . . 711
domain EXPR Expression . . . 715
Expression (EXPR) . . . 723
domain EXPUPXS ExponentialOfUnivariatePuiseuxSeries . . . 735
ExponentialOfUnivariatePuiseuxSeries (EXPUPXS) . . . 739
domain EAB ExtAlgBasis . . . 742
ExtAlgBasis (EAB) . . . 743
domain E04DGFA e04dgfAnnaType . . . 745
e04dgfAnnaType (E04DGFA) . . . 747
domain E04FDFA e04fdfAnnaType . . . 749

domain E04GCFA e04gcfAnnaType . . . 753
e04gcfAnnaType (E04GCFA) . . . 754
domain E04JAFA e04jafAnnaType . . . 757
e04jafAnnaType (E04JAFA) . . . 758
domain E04MBFA e04mbfAnnaType . . . 760
e04mbfAnnaType (E04MBFA) . . . 762
domain E04NAFA e04nafAnnaType . . . 764
e04nafAnnaType (E04NAFA) . . . 765
domain E04UCFA e04ucfAnnaType . . . 767
e04ucfAnnaType (E04UCFA) . . . 769

7 Chapter F **773**
domain FR Factored . . . 773
Factored (FR) . . . 786
domain FILE File . . . 797
File (FILE) . . . 802
domain FNAME FileName . . . 804
FileName (FNAME) . . . 810
domain FDIV FiniteDivisor . . . 811
FiniteDivisor (FDIV) . . . 813
domain FF FiniteField . . . 816
FiniteField (FF) . . . 819
domain FFCG FiniteFieldCyclicGroup . . . 821
FiniteFieldCyclicGroup (FFCG) . . . 824
domain FFCGX FiniteFieldCyclicGroupExtension . . . 826
FiniteFieldCyclicGroupExtension (FFCGX) . . . 829
domain FFCGP FiniteFieldCyclicGroupExtensionByPolynomial . . . 831
FiniteFieldCyclicGroupExtensionByPolynomial (FFCGP) . . . 834
domain FFX FiniteFieldExtension . . . 842
FiniteFieldExtension (FFX) . . . 845
domain FFP FiniteFieldExtensionByPolynomial . . . 847
FiniteFieldExtensionByPolynomial (FFP) . . . 850
domain FFNB FiniteFieldNormalBasis . . . 856
FiniteFieldNormalBasis (FFNB) . . . 859

domain FFNBX FiniteFieldNormalBasisExtension . . . 861
FiniteFieldNormalBasisExtension (FFNBX) . . . 865
domain FFNBP FiniteFieldNormalBasisExtensionByPolynomial . . . 867
FiniteFieldNormalBasisExtensionByPolynomial (FFNBP) . . . 871
domain FARRAY FlexibleArray . . . 880
FlexibleArray (FARRAY) . . . 885
domain FLOAT Float . . . 887
Float (FLOAT) . . . 908
domain FC FortranCode . . . 929
FortranCode (FC) . . . 931
domain FEXPR FortranExpression . . . 943
FortranExpression (FEXPR) . . . 946
domain FORTRAN FortranProgram . . . 954
FortranProgram (FORTRAN) . . . 955
domain FST FortranScalarType . . . 960
FortranScalarType (FST) . . . 962
domain FTEM FortranTemplate . . . 965
FortranTemplate (FTEM) . . . 967
domain FT FortranType . . . 969
FortranType (FT) . . . 971
domain FCOMP FourierComponent . . . 973
FourierComponent (FCOMP) . . . 975
domain FSERIES FourierSeries . . . 976
FourierSeries (FSERIES) . . . 978
domain FRAC Fraction . . . 980
Fraction (FRAC) . . . 985
domain FRIDEAL FractionalIdeal . . . 993
FractionalIdeal (FRIDEAL) . . . 994
domain FRMOD FramedModule . . . 998
FramedModule (FRMOD) . . . 1000
domain FAGROUP FreeAbelianGroup . . . 1002
FreeAbelianGroup (FAGROUP) . . . 1004
domain FAMONOID FreeAbelianMonoid . . . 1006
FreeAbelianMonoid (FAMONOID) . . . 1007
domain FGROUP FreeGroup . . . 1008
FreeGroup (FGROUP) . . . 1010
domain FM FreeModule . . . 1012
FreeModule (FM) . . . 1013
domain FM1 FreeModule1 . . . 1015
FreeModule1 (FM1) . . . 1016
domain FMONOID FreeMonoid . . . 1019
FreeMonoid (FMONOID) . . . 1021
domain FNLA FreeNilpotentLie . . . 1025
FreeNilpotentLie (FNLA) . . . 1027
domain FPARFRAC FullPartialFractionExpansion . . . 1030
FullPartialFractionExpansion (FPARFRAC) . . . 1040

domain FUNCTION FunctionCalled . . . 1044
FunctionCalled (FUNCTION) . . . 1045

8 Chapter G **1047**
domain GDMP GeneralDistributedMultivariatePolynomial . . . 1047
GeneralDistributedMultivariatePolynomial (GDMP) . . . 1052
domain GMODPOL GeneralModulePolynomial . . . 1058
GeneralModulePolynomial (GMODPOL) . . . 1059
domain GCNAALG GenericNonAssociativeAlgebra . . . 1061
GenericNonAssociativeAlgebra (GCNAALG) . . . 1064
domain GPOLSET GeneralPolynomialSet . . . 1072
GeneralPolynomialSet (GPOLSET) . . . 1074
domain GSTBL GeneralSparseTable . . . 1076
GeneralSparseTable (GSTBL) . . . 1078
domain GTSET GeneralTriangularSet . . . 1080
GeneralTriangularSet (GTSET) . . . 1082
domain GSERIES GeneralUnivariatePowerSeries . . . 1086
GeneralUnivariatePowerSeries (GSERIES) . . . 1089
domain GRIMAGE GraphImage . . . 1093
GraphImage (GRIMAGE) . . . 1094
domain GOPT GuessOption . . . 1103
GuessOption (GOPT) . . . 1104
domain GOPT0 GuessOptionFunctions0 . . . 1108
GuessOptionFunctions0 (GOPT0) . . . 1110

9 Chapter H **1117**
domain HASHTBL HashTable . . . 1117
HashTable (HASHTBL) . . . 1120
domain HEAP Heap . . . 1121
Heap (HEAP) . . . 1134
domain HEXADEC HexadecimalExpansion . . . 1139
HexadecimalExpansion (HEXADEC) . . . 1142
package HTMLFORM HTMLFormat . . . 1144
Overview . . . 1144
Why output to HTML? . . . 1145
Using the formatter . . . 1145
Form of the output . . . 1146
Matrix Formatting . . . 1146
Programmers Guide . . . 1146
Future Developments . . . 1147
HTMLFormat (HTMLFORM) . . . 1152
domain HDP HomogeneousDirectProduct . . . 1169
HomogeneousDirectProduct (HDP) . . . 1172

New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))

Chapter 1

Chapter Overview

This book contains the domains in Axiom, in alphabetical order.

Each domain has an associated 'dotpic' chunk which only lists the domains, categories, and packages that are in the layer immediately below in the build order. For the full list see the algebra Makefile where this information is maintained.

Each domain is preceded by a picture. The picture indicates several things. The colors indicate whether the name refers to a category, domain, or package. An ellipse means that the name refers to something in the bootstrap set. Thus,

— Any.help —

```
=====================================================================
Any examples
=====================================================================

Any implements a type that packages up objects and their types in
objects of Any. Roughly speaking that means that if s : S then when
converted to Any, the new object will include both the original object
and its type. This is a way of converting arbitrary objects into a
single type without losing any of the original information. Any object
can be converted to one of Any.

So we can convert a list to type Any

a:Any := [1,2]
   [1,2]

and another list to type Any

b:Any := [1,2]
   [1,2]

Equality works
```

```
(a = b)@Boolean
   true

We can compare the Any type with other types:

c := [1,2]

typeOf a

typeOf c

(a = c)@Boolean

If the values are differennt than we see the difference:

b := [1,3]
   [1,3]

(a = b)@Boolean
    false

The Any type works with many types:

a := "A"
    "A"

(a = b)@Boolean
    false

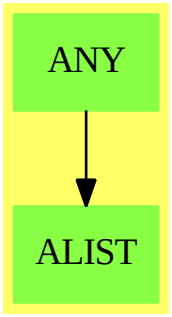
b := "A"
    "A"

(a = b)@Boolean
   true

This is true for more complex types:

Sae := SAE(FRAC INT, UP(x, FRAC INT), x^2-3)

a := generator()$Sae
   x



b := generator()$Sae
   x

(a = b)@Boolean
   true

          ++ original object that was converted to \spadtype{Any}.
        obj             : % -> None
          ++ obj(a) essentially returns the original object that was
          ++ converted to \spadtype{Any} except that the type is forced
          ++ to be \spadtype{None}.
        showTypeInOutput: Boolean -> String
          ++ showTypeInOutput(bool) affects the way objects of
          ++ \spadtype{Any} are displayed. If \spad{bool} is true
          ++ then the type of the original object that was converted
          ++ to \spadtype{Any} will be printed. If \spad{bool} is
          ++ false, it will not be printed.

=====================================================================
ArrayStack examples
=====================================================================

An ArrayStack object is represented as a list ordered by last-in, first-out.
It operates like a pile of books, where the "next" book is the one
on the top of the pile.

Here we create an array stack of integers from a list. Notice that the
order in the list is the order in the stack.

   a:ArrayStack INT:= arrayStack [1,2,3,4,5]
      [1,2,3,4,5]

We can remove the top of the stack using pop!:

   pop! a
      1

Notice that the use of pop! is destructive (destructive operations
in Axiom usually end with ! to indicate that the underylying data
structure is changed).

   a
      [2,3,4,5]
```

```
The extract! operation is another name for the pop! operation and
has the same effect. This operation treats the stack as a BagAggregate:

   extract! a
      2

and you can see that it also has destructively modified the stack:

   a
      [3,4,5]

Next we push a new element on top of the stack:

   push!(9,a)
      9

Again, the push! operation is destructive so the stack is changed:

   a
      [9,3,4,5]

Another name for push! is insert!, which treats the stack as a BagAggregate:

   insert!(8,a)
      [8,9,3,4,5]

and it modifies the stack:

   a
      [8,9,3,4,5]

The inspect function returns the top of the stack without modification,
viewed as a BagAggregate:

   inspect a
      8

The empty? operation returns true only if there are no element on the
stack, otherwise it returns false:

   empty? a
      false

The top operation returns the top of stack without modification, viewed
as a Stack:

   top a
      8
```

The depth operation returns the number of elements on the stack:

```
   depth a
      5
```

which is the same as the # (length) operation:

```
   #a
       5
```

The less? predicate will compare the stack length to an integer:

```
   less?(a,9)
        true
```

The more? predicate will compare the stack length to an integer:

```
   more?(a,9)
        false
```

The size? operation will compare the stack length to an integer:

```
   size?(a,#a)
        true
```

and since the last computation must alwasy be true we try:

```
   size?(a,9)
        false
```

The parts function will return the stack as a list of its elements:

```
   parts a
        [8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a stack.
Notice that the elements are pushed in reverse order:

```
   bag([1,2,3,4,5])$ArrayStack(INT)
        [5,4,3,2,1]
```

The empty function will construct an empty stack of a given type:

```
   b:=empty()$(ArrayStack INT)
        []
```

and the empty? predicate allows us to find out if a stack is empty:

```
   empty? b
        true
```

```
The sample function returns a sample, empty stack:

   sample()$ArrayStack(INT)
        []

We can copy a stack and it does not share storage so subsequent
modifications of the original stack will not affect the copy:

   c:=copy a
        [8,9,3,4,5]

The eq? function is only true if the lists are the same reference,
so even though c is a copy of a, they are not the same:

   eq?(a,c)
        false

However, a clearly shares a reference with itself:

   eq?(a,a)
        true

But we can compare a and c for equality:

   (a=c)@Boolean
        true

and clearly a is equal to itself:

   (a=a)@Boolean
        true

and since a and c are equal, they are clearly NOT not-equal:

   a~=c
        false

We can use the any? function to see if a predicate is true for any element:

   any?(x+->(x=4),a)
        true

or false for every element:

   any?(x+->(x=11),a)
        false

We can use the every? function to check every element satisfies a predicate:
```

```
   every?(x+->(x=11),a)
        false
```

We can count the elements that are equal to an argument of this type:

```
   count(4,a)
        1
```

or we can count against a boolean function:

```
   count(x+->(x>2),a)
        5
```

You can also map a function over every element, returning a new stack:

```
   map(x+->x+10,a)
        [18,19,13,14,15]
```

Notice that the orignal stack is unchanged:

```
   a
        [8,9,3,4,5]
```

You can use map! to map a function over every element and change
the original stack since map! is destructive:

```
   map!(x+->x+10,a)
       [18,19,13,14,15]
```

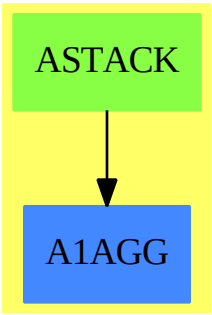
Notice that the orignal stack has been changed:

```
   a
       [18,19,13,14,15]
```

The member function can also get the element of the stack as a list:

```
   members a
       [18,19,13,14,15]
```

and using member? we can test if the stack holds a given element:



```
   member?(14,a)
       true
```

)abbrev domain ASP24 Asp24
++ Author: Mike Dewar, Grant Keady and Godfrey Nolan
++ Date Created: Mar 1993
++ Date Last Updated: 6 October 1994
++ Description:
++\spadtype{Asp24} produces Fortran for Type 24 ASPs which evaluate a
++multivariate function at a point (needed for NAG routine e04jaf),
++for example:
++
++\tab{5}SUBROUTINE FUNCT1(N,XC,FC)\br
++\tab{5}DOUBLE PRECISION FC,XC(N)\br
++\tab{5}INTEGER N\br
++\tab{5}FC=10.0D0*XC(4)**4+(-40.0D0*XC(1)*XC(4)**3)+(60.0D0*XC(1)**2+5\br
++\tab{4}&.0D0)*XC(4)**2+((-10.0D0*XC(3))+(-40.0D0*XC(1)**3))*XC(4)+16.0D0*X\br
++\tab{4}&C(3)**4+(-32.0D0*XC(2)*XC(3)**3)+(24.0D0*XC(2)**2+5.0D0)*XC(3)**2+\br
++\tab{4}&(-8.0D0*XC(2)**3*XC(3))+XC(2)**4+100.0D0*XC(2)**2+20.0D0*XC(1)*XC(\br
++\tab{4}&2)+10.0D0*XC(1)**4+XC(1)**2\br
++\tab{5}RETURN\br
++\tab{5}END\br

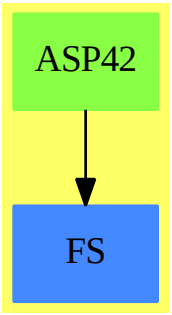
Asp42 examples
=====================================================================



Asp42 produces Fortran for Type 42 ASPs, needed for NAG routines d02raf
and d02saf in particular.  These ASPs are in fact three Fortran routines
which return a vector of functions, and their derivatives wrt Y(i) and
also a continuation parameter EPS, for example:

  SUBROUTINE G(EPS,YA,YB,BC,N)
  DOUBLE PRECISION EPS,YA(N),YB(N),BC(N)
  INTEGER N
  BC(1)=YA(1)
  BC(2)=YA(2)
  BC(3)=YB(2)-1.0D0
  RETURN
  END
  SUBROUTINE JACOBG(EPS,YA,YB,AJ,BJ,N)
  DOUBLE PRECISION EPS,YA(N),AJ(N,N),BJ(N,N),YB(N)
  INTEGER N
  AJ(1,1)=1.0D0
  AJ(1,2)=0.0D0
  AJ(1,3)=0.0D0
```

```
  AJ(2,1)=0.0D0
  AJ(2,2)=1.0D0
  AJ(2,3)=0.0D0
  AJ(3,1)=0.0D0
  AJ(3,2)=0.0D0
  AJ(3,3)=0.0D0
  BJ(1,1)=0.0D0
  BJ(1,2)=0.0D0
  BJ(1,3)=0.0D0
  BJ(2,1)=0.0D0
  BJ(2,2)=0.0D0
  BJ(2,3)=0.0D0
  BJ(3,1)=0.0D0
  BJ(3,2)=1.0D0
  BJ(3,3)=0.0D0
  RETURN
  END
  SUBROUTINE JACGEP(EPS,YA,YB,BCEP,N)
  DOUBLE PRECISION EPS,YA(N),YB(N),BCEP(N)
  INTEGER N
  BCEP(1)=0.0D0
  BCEP(2)=0.0D0

Asp55 produces Fortran for Type 55 ASPs, needed for NAG routines
e04dgf and e04ucf, for example:

  SUBROUTINE CONFUN(MODE,NCNLN,N,NROWJ,NEEDC,X,C,CJAC,NSTATE,IUSER
  &,USER)
  DOUBLE PRECISION C(NCNLN),X(N),CJAC(NROWJ,N),USER(*)
  INTEGER N,IUSER(*),NEEDC(NCNLN),NROWJ,MODE,NCNLN,NSTATE
  IF(NEEDC(1).GT.0)THEN
```

```
  C(1)=X(6)**2+X(1)**2
  CJAC(1,1)=2.0D0*X(1)
  CJAC(1,2)=0.0D0
  CJAC(1,3)=0.0D0
  CJAC(1,4)=0.0D0
  CJAC(1,5)=0.0D0
  CJAC(1,6)=2.0D0*X(6)
  ENDIF
  IF(NEEDC(2).GT.0)THEN
  C(2)=X(2)**2+(-2.0D0*X(1)*X(2))+X(1)**2
  CJAC(2,1)=(-2.0D0*X(2))+2.0D0*X(1)
  CJAC(2,2)=2.0D0*X(2)+(-2.0D0*X(1))
  CJAC(2,3)=0.0D0
  CJAC(2,4)=0.0D0
  CJAC(2,5)=0.0D0
  CJAC(2,6)=0.0D0
  ENDIF
  IF(NEEDC(3).GT.0)THEN
  C(3)=X(3)**2+(-2.0D0*X(1)*X(3))+X(2)**2+X(1)**2
  CJAC(3,1)=(-2.0D0*X(3))+2.0D0*X(1)
  CJAC(3,2)=2.0D0*X(2)

Asp7 produces Fortran for Type 7 ASPs, needed for NAG routines
d02bbf, d02gaf. These represent a vector of functions of the scalar X and
the array Z, and look like:

  SUBROUTINE FCN(X,Z,F)
  DOUBLE PRECISION F(*),X,Z(*)
  F(1)=DTAN(Z(3))
  F(2)=((-0.03199999999999999D0*DCOS(Z(3))*DTAN(Z(3)))+(-0.02D0*Z(2)
  &**2))/(Z(2)*DCOS(Z(3)))
  F(3)=-0.03199999999999999D0/(X*Z(2)**2)
  RETURN
  END

=====================================================================
Asp9 examples
=====================================================================

Asp9 produces Fortran for Type 9 ASPs, needed for NAG routines
d02bhf, d02cjf, d02ejf.
These ASPs represent a function of a scalar X and a vector Y, for example:

 DOUBLE PRECISION FUNCTION G(X,Y)
 DOUBLE PRECISION X,Y(*)
 G=X+Y(1)
 RETURN
 END

If the user provides a constant value for G, then extra information is added
via COMMON blocks used by certain routines.  This specifies that the value
returned by G in this case is to be ignored.

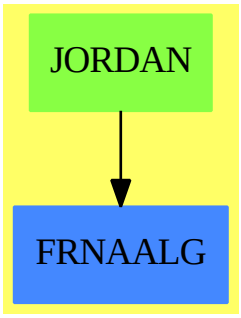
— AssociatedJordanAlgebra.help —

```
=====================================================================
AssociatedJordanAlgebra examples
=====================================================================

AssociatedJordanAlgebra takes an algebra A and uses *$A to define the
new multiplications
      a*b := (a *$A b + b *$A a)/2     (anticommutator)

The usual notation {a,b}_+ cannot be used due to restrictions in the
current language.



This domain only gives a Jordan algebra if the Jordan-identity
     (a*b)*c + (b*c)*a + (c*a)*b = 0
holds for all a, b, c in A.
This relation can be checked by jordanAdmissible?()$A.

If the underlying algebra is of type FramedNonAssociativeAlgebra(R)
(i.e. a non-associative algebra over R which is a free R-module of finite
rank, together with a fixed R-module basis), then the same is true for the
associated Jordan algebra. Moreover, if the underlying algebra is of type
FiniteRankNonAssociativeAlgebra(R) (i.e. a non-associative algebra over R
which is a free R-module of finite rank), then the same true for the
associated Jordan algebra.

— domain JORDAN AssociatedJordanAlgebra —

```
)abbrev domain JORDAN AssociatedJordanAlgebra
++ Author: J. Grabmeier
++ Date Created: 14 June 1991
++ Date Last Updated: 14 June 1991
++ Description:
++ AssociatedJordanAlgebra takes an algebra \spad{A} and uses \spadfun{*$A}
++ to define the new multiplications \spad{a*b := (a *$A b + b *$A a)/2}
++ (anticommutator).
++ The usual notation \spad{{a,b}_+} cannot be used due to
```

```
++ restrictions in the current language.
++ This domain only gives a Jordan algebra if the
++ Jordan-identity \spad{(a*b)*c + (b*c)*a + (c*a)*b = 0} holds
++ for all \spad{a},\spad{b},\spad{c} in \spad{A}.
++ This relation can be checked by
++ \spadfun{jordanAdmissible?()$A}.
++
++ If the underlying algebra is of type
++ \spadtype{FramedNonAssociativeAlgebra(R)} (i.e. a non
++ associative algebra over R which is a free R-module of finite
++ rank, together with a fixed R-module basis), then the same
++ is true for the associated Jordan algebra.
++ Moreover, if the underlying algebra is of type
++ \spadtype{FiniteRankNonAssociativeAlgebra(R)} (i.e. a non
++ associative algebra over R which is a free R-module of finite
++ rank), then the same true for the associated Jordan algebra.

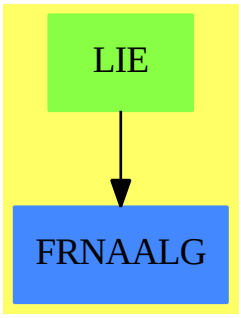
=====================================================================
AssociatedLieAlgebra examples
=====================================================================



AssociatedLieAlgebra takes an algebra A and uses *$A to define the
Lie bracket
    a*b := (a *$A b - b *$A a) (commutator).
Note that the notation [a,b] cannot be used due to restrictions of the
current compiler. This domain only gives a Lie algebra if the
Jacobi-identity
   (a*b)*c + (b*c)*a + (c*a)*b = 0
holds for all a, b, c in A. This relation can be checked by
lieAdmissible?()$A.

If the underlying algebra is of type FramedNonAssociativeAlgebra(R)
(i.e. a non-associative algebra over R which is a free R-module of finite
rank, together with a fixed R-module basis), then the same is true for the
associated Lie algebra. Also, if the underlying algebra is of type
FiniteRankNonAssociativeAlgebra(R) (i.e. a non-associative algebra over R
which is a free R-module of finite rank), then the same is true for the
associated Lie algebra.

— AssociationList.help —

```
=====================================================================
AssociationList examples
=====================================================================

AssociationList implements association lists. These may be viewed as
lists of pairs where the first part is a key and the second is the
stored value. For example, the key might be a string with a persons
employee identification number and the value might be a record with
personnel data.

The AssociationList constructor provides a general structure for
associative storage.  This type provides association lists in which
data objects can be saved according to keys of any type.  For a given
association list, specific types must be chosen for the keys and
entries.  You can think of the representation of an association list
as a list of records with key and entry fields.

Association lists are a form of table and so most of the operations
available for Table are also available for AssociationList.  They can
also be viewed as lists and can be manipulated accordingly.

This is a Record type with age and gender fields.

  Data := Record(monthsOld : Integer, gender : String)
    Record(monthsOld: Integer,gender: String)
                      Type: Domain

In this expression, al is declared to be an association
list whose keys are strings and whose entries are the above records.

  al : AssociationList(String,Data)
                      Type: Void

The table operation is used to create an empty association list.

  al := table()
   table()
    Type: AssociationList(String,Record(monthsOld: Integer,gender: String))
```

```
You can use assignment syntax to add things to the association list.

  al."bob" := [407,"male"]$Data
   [monthsOld=407, gender= "male"]
                      Type: Record(monthsOld: Integer,gender: String)

  al."judith" := [366,"female"]$Data
   [monthsOld=366, gender= "female"]
                      Type: Record(monthsOld: Integer,gender: String)

  al."katie" := [24,"female"]$Data
   [monthsOld=24, gender= "female"]
                      Type: Record(monthsOld: Integer,gender: String)

Perhaps we should have included a species field.

  al."smokie" := [200,"female"]$Data
   [monthsOld=200, gender= "female"]
                      Type: Record(monthsOld: Integer,gender: String)

Now look at what is in the association list.  Note that the last-added
(key, entry) pair is at the beginning of the list.

  al
   table("smokie" = [monthsOld=200, gender= "female"],
         "katie" = [monthsOld=24, gender= "female"],
         "judith" = [monthsOld=366, gender= "female"],
         "bob" = [monthsOld=407, gender= "male"])
      Type: AssociationList(String,Record(monthsOld: Integer,gender: String))

You can reset the entry for an existing key.

  al."katie" := [23,"female"]$Data
   [monthsOld=23, gender= "female"]
                      Type: Record(monthsOld: Integer,gender: String)

Use delete! to destructively remove an element of the association
list.  Use delete to return a copy of the association list with the
element deleted.  The second argument is the index of the element to
delete.

  delete!(al,1)
   table("katie" = [monthsOld=23, gender= "female"],
         "judith" = [monthsOld=366, gender= "female"],
         "bob" = [monthsOld=407, gender= "male"])
    Type: AssociationList(String,Record(monthsOld: Integer,gender: String))

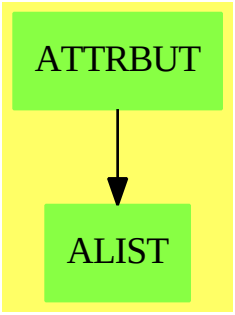
AttributeButtons examples
=====================================================================

AttributeButtons implements a database and associated adjustment
mechanisms for a set of attributes.

For ODEs these attributes are "stiffness", "stability" (i.e. how much
affect the cosine or sine component of the solution has on the stability of
the result), "accuracy" and "expense" (i.e. how expensive is the evaluation
of the ODE).  All these have bearing on the cost of calculating the
solution given that reducing the step-length to achieve greater accuracy
requires considerable number of evaluations and calculations.



The effect of each of these attributes can be altered by increasing or
decreasing the button value.

For Integration there is a button for increasing and decreasing the preset
number of function evaluations for each method.  This is automatically used
```

```
by ANNA when a method fails due to insufficient workspace or where the
limit of function evaluations has been reached before the required
accuracy is achieved.

====================================================================
BalancedBinaryTree examples
====================================================================

BalancedBinaryTree(S) is the domain of balanced binary trees (bbtree).
A balanced binary tree of 2**k leaves, for some k > 0, is symmetric,
that is, the left and right subtree of each interior node have identical
shape. In general, the left and right subtree of a given node can differ
 by at most leaf node.

BalancedBinaryTrees(S) is the domain of balanced binary trees with
elements of type S at the nodes.  A binary tree is either empty or
else consists of a node having a value and two branches, each branch a
binary tree.  A balanced binary tree is one that is balanced with
respect its leaves.  One with 2^k leaves is perfectly "balanced": the
tree has minimum depth, and the left and right branch of every
interior node is identical in shape.

Balanced binary trees are useful in algebraic computation for
so-called "divide-and-conquer" algorithms.  Conceptually, the data
for a problem is initially placed at the root of the tree.  The
original data is then split into two subproblems, one for each
subtree.  And so on.  Eventually, the problem is solved at the leaves
of the tree.  A solution to the original problem is obtained by some
mechanism that can reassemble the pieces.  In fact, an implementation
of the Chinese Remainder Algorithm using balanced binary trees was
first proposed by David Y. Y.  Yun at the IBM T. J.  Watson Research
Center in Yorktown Heights, New York, in 1978.  It served as the
prototype for polymorphic algorithms in Axiom.

In what follows, rather than perform a series of computations with a
single expression, the expression is reduced modulo a number of
integer primes, a computation is done with modular arithmetic for each
prime, and the Chinese Remainder Algorithm is used to obtain the
answer to the original problem.  We illustrate this principle with the
```

```
computation of 12^2 = 144.

A list of moduli:

  lm := [3,5,7,11]
   [3,5,7,11]
                      Type: PositiveInteger

The expression modTree(n, lm) creates a balanced binary tree with leaf
values n mod m for each modulus m in lm.

  modTree(12,lm)
   [0, 2, 5, 1]
                      Type: List Integer

Operation modTree does this using operations on balanced binary trees.
We trace its steps.  Create a balanced binary tree t of zeros with
four leaves.

  t := balancedBinaryTree(#lm, 0)
   [[0, 0, 0], 0, [0, 0, 0]]
                      Type: BalancedBinaryTree NonNegativeInteger

The leaves of the tree are set to the individual moduli.

  setleaves!(t,lm)
   [[3, 0, 5], 0, [7, 0, 11]]
                      Type: BalancedBinaryTree NonNegativeInteger

mapUp! to do a bottom-up traversal of t, setting each interior node to
the product of the values at the nodes of its children.

  mapUp!(t,_*)
   1155
                      Type: PositiveInteger

The value at the node of every subtree is the product of the moduli
of the leaves of the subtree.

  t
   [[3, 15, 5], 1155, [7, 77, 11]]
                      Type: BalancedBinaryTree NonNegativeInteger

Operation mapDown!(t,a,fn) replaces the value v at each node of t by
fn(a,v).

  mapDown!(t,12,_rem)
   [[0, 12, 2], 12, [5, 12, 1]]
                      Type: BalancedBinaryTree NonNegativeInteger
```

```
The operation leaves returns the leaves of the resulting tree.  In
this case, it returns the list of 12 mod m for each modulus m.

  leaves %
   [0, 2, 5, 1]
                        Type: List NonNegativeInteger

Compute the square of the images of 12 modulo each m.

  squares := [x**2 rem m for x in % for m in lm]
   [0, 4, 4, 1]
                        Type: List NonNegativeInteger

Call the Chinese Remainder Algorithm to get the answer for 12^2.

  chineseRemainder(%,lm)
   144
                        Type: PositiveInteger

— domain BBTREE BalancedBinaryTree —

```
)abbrev domain BBTREE BalancedBinaryTree
++ Description:
++ \spadtype{BalancedBinaryTree(S)} is the domain of balanced
++ binary trees (bbtree). A balanced binary tree of \spad{2**k} leaves,
++ for some \spad{k > 0}, is symmetric, that is, the left and right
++ subtree of each interior node have identical shape.
++ In general, the left and right subtree of a given node can differ
++ by at most leaf node.

— BasicOperator.help —

```
====================================================================
BasicOperator examples
====================================================================

A basic operator is an object that can be symbolically applied to a
list of arguments from a set, the result being a kernel over that set
or an expression.

You create an object of type BasicOperator by using the operator
operation.  This first form of this operation has one argument and it
must be a symbol.  The symbol should be quoted in case the name has
been used as an identifier to which a value has been assigned.
```

```
A frequent application of BasicOperator is the creation of an operator
to represent the unknown function when solving a differential equation.

Let y be the unknown function in terms of x.

  y := operator 'y
   y
                      Type: BasicOperator

This is how you enter the equation y'' + y' + y = 0.

  deq := D(y x, x, 2) + D(y x, x) + y x = 0
    ,,       ,
   y  (x) + y (x) + y(x) = 0
                      Type: Equation Expression Integer

To solve the above equation, enter this.

  solve(deq, y, x)
                                          x     x
                                +-+   - -   - -      +-+
                               x\|3      2     2    x\|3
   [particular= 0,basis= [cos(-----)%e   ,%e   sin(-----)]]
                                 2                    2
                      Type: Union(Record(particular: Expression Integer,
                                  basis: List Expression Integer),...)

Use the single argument form of BasicOperator (as above) when you
intend to use the operator to create functional expressions with an
arbitrary number of arguments

Nary means an arbitrary number of arguments can be used in the
functional expressions.

  nary? y
   true
                      Type: Boolean

  unary? y
   false
                      Type: Boolean

Use the two-argument form when you want to restrict the number of
arguments in the functional expressions created with the operator.

This operator can only be used to create functional expressions
with one argument.

  opOne := operator('opOne, 1)
   opOne
```

```
                    Type: BasicOperator

  nary? opOne
   false
                    Type: Boolean

  unary? opOne
   true
                    Type: Boolean
```

Use arity to learn the number of arguments that can be used. It returns "false" if the operator is nary.

```
  arity opOne
   1
                    Type: Union(NonNegativeInteger,...)
```

Use name to learn the name of an operator.

```
  name opOne
   opOne
                    Type: Symbol
```

Use is? to learn if an operator has a particular name.

```
  is?(opOne, 'z2)
   false
                    Type: Boolean
```

You can also use a string as the name to be tested against.

```
  is?(opOne, "opOne")
   true
                    Type: Boolean
```

You can attached named properties to an operator. These are rarely used at the top-level of the Axiom interactive environment but are used with Axiom library source code.

By default, an operator has no properties.

```
  properties y
   table()
                    Type: AssociationList(String,None)
```

The interface for setting and getting properties is somewhat awkward because the property values are stored as values of type None.

Attach a property by using setProperty.

```
  setProperty(y, "use", "unknown function" :: None )
   y
                      Type: BasicOperator

  properties y
   table("use"=NONE)
                      Type: AssociationList(String,None)

We know the property value has type String.

  property(y, "use") :: None pretend String
   "unknown function"
                      Type: String

Use deleteProperty! to destructively remove a property.

 deleteProperty!(y, "use")
  y
                      Type: BasicOperator

  properties y
   table()
                      Type: AssociationList(String,None)

++ Description:
++ Basic system operators.
++ A basic operator is an object that can be applied to a list of
++ arguments from a set, the result being a kernel over that set.

BasicOperator(): Exports == Implementation where
  O   ==> OutputForm
  P   ==> AssociationList(String, None)
  L   ==> List Record(key:String, entry:None)
  SEX ==> InputForm
-- some internal properties
  LESS?   ==> "%less?"
  EQUAL?  ==> "%equal?"
  WEIGHT  ==> "%weight"
  DISPLAY ==> "%display"
  SEXPR   ==> "%input"

  Exports ==> OrderedSet with
    name      : $ -> Symbol
      ++ name(op) returns the name of op.
    properties: $ -> P
      ++ properties(op) returns the list of all the properties
      ++ currently attached to op.
    copy      : $ -> $
      ++ copy(op) returns a copy of op.
    operator  : Symbol -> $
      ++ operator(f) makes f into an operator with arbitrary arity.
    operator  : (Symbol, NonNegativeInteger) -> $
      ++ operator(f, n) makes f into an n-ary operator.
    arity     : $ -> Union(NonNegativeInteger, "failed")
      ++ arity(op) returns n if op is n-ary, and
      ++ "failed" if op has arbitrary arity.
    nullary?  : $ -> Boolean
```

```
  ++ nullary?(op) tests if op is nullary.
unary?    : $ -> Boolean
  ++ unary?(op) tests if op is unary.
nary?     : $ -> Boolean
  ++ nary?(op) tests if op has arbitrary arity.
weight    : $ -> NonNegativeInteger
  ++ weight(op) returns the weight attached to op.
weight    : ($, NonNegativeInteger) -> $
  ++ weight(op, n) attaches the weight n to op.
equality  : ($, ($, $) -> Boolean) -> $
  ++ equality(op, foo?) attaches foo? as the "%equal?" property
  ++ to op. If op1 and op2 have the same name, and one of them
  ++ has an "%equal?" property f, then \spad{f(op1, op2)} is called to
  ++ decide whether op1 and op2 should be considered equal.
comparison : ($, ($, $) -> Boolean) -> $
  ++ comparison(op, foo?) attaches foo? as the "%less?" property
  ++ to op. If op1 and op2 have the same name, and one of them
  ++ has a "%less?" property f, then \spad{f(op1, op2)} is called to
  ++ decide whether \spad{op1 < op2}.
display   : $ -> Union(List O -> O, "failed")
  ++ display(op) returns the "%display" property of op if
  ++ it has one attached, and "failed" otherwise.
display   : ($, List O -> O)      -> $
  ++ display(op, foo) attaches foo as the "%display" property
  ++ of op. If op has a "%display" property f, then \spad{op(a1,...,an)}
  ++ gets converted to OutputForm as \spad{f(a1,...,an)}.
display   : ($, O -> O)           -> $
  ++ display(op, foo) attaches foo as the "%display" property
  ++ of op. If op has a "%display" property f, then \spad{op(a)}
  ++ gets converted to OutputForm as \spad{f(a)}.
  ++ Argument op must be unary.
input     : ($, List SEX -> SEX)  -> $
  ++ input(op, foo) attaches foo as the "%input" property
  ++ of op. If op has a "%input" property f, then \spad{op(a1,...,an)}
  ++ gets converted to InputForm as \spad{f(a1,...,an)}.
input     : $ -> Union(List SEX -> SEX, "failed")
  ++ input(op) returns the "%input" property of op if
  ++ it has one attached, "failed" otherwise.
is?       : ($, Symbol) -> Boolean
  ++ is?(op, s) tests if the name of op is s.
has?      : ($, String) -> Boolean
  ++ has?(op, s) tests if property s is attached to op.
assert    : ($, String) -> $
  ++ assert(op, s) attaches property s to op.
  ++ Argument op is modified "in place", i.e. no copy is made.
deleteProperty_!: ($, String) -> $
  ++ deleteProperty!(op, s) unattaches property s from op.
  ++ Argument op is modified "in place", i.e. no copy is made.
property     : ($, String) -> Union(None, "failed")
  ++ property(op, s) returns the value of property s if
```

```
      ++ it is attached to op, and "failed" otherwise.
    setProperty   : ($, String, None) -> $
      ++ setProperty(op, s, v) attaches property s to op,
      ++ and sets its value to v.
      ++ Argument op is modified "in place", i.e. no copy is made.
    setProperties : ($, P) -> $
      ++ setProperties(op, l) sets the property list of op to l.
      ++ Argument op is modified "in place", i.e. no copy is made.

=====================================================================
BasicStochasticDifferential examples
=====================================================================

Based on Symbol: a domain of symbols representing basic stochastic
differentials, used in StochasticDifferential(R) in the underlying
sparse multivariate polynomial representation.

We create new BSD only by coercion from Symbol using a special
function introduce! first of all to add to a private set SDset. We
allow a separate function convertIfCan which will check whether the
argument has previously been declared as a BSD.

The copyBSD() returns setBSD as a list of BSD.
Initially the BSD table of symbols is empty:
   print copyBSD()
      []

as is the Ito table. The copyIto() returns the table relating
semimartingales to basic stochastic differentials.
```

```
   print copyIto()
      table()

We introduce a new stochastic differential:
   dX:=introduce!(X,dX) -- dX is a new stochastic differential
      dX

and now it is in the BSD table of symbols:
   print copyBSD()
      [dX]

and the Ito table:
   print copyIto()
      table(X= dX)

The getSmgl(bsd) returns the semimartingale S related to the basic
stochastic differential bsd by introduce!:
   getSmgl(dX)
      X

Note that the dX symbol is of type BasicStochasticDifferential:
   print domainOf(dX)
     BasicStochasticDifferential()

The d function, d(X) returns dX if tableIto(X)=dX otherwise 0:
   print d X
      dX

and we can specify the domain:
   print ((d$BSD) X)
      dX

which clearly is of domain BasicStochasticDifferential
   print domainOf((d$BSD) X)
      BasicStochasticDifferential()

The introduce!(X,dX) returns dX as BSD if it isn't already in BSD
   introduce!(t,dt) -- dt is a new stochastic differential
       dt

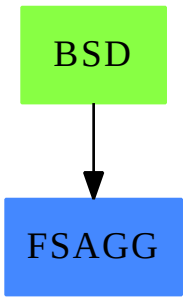
Now we can see that dt is in the BSD table:
   print copyBSD()
       [dX,dt]

and the Ito table:
   print copyIto()
       table(t= dt,X= dX)

You cannot repeat an introduce! for an existing entry:
```

```
   introduce!(t,dt)
       "failed"

Regular symbols can be added, especially with subscripts:
   [introduce!(A[i],dA[i]) for i in 1..2]
             [dA ,dA ]
                1   2



And we can see them in the BSD table:
   print copyBSD()
      [dA ,dA ,dX,dt]
         1   2

and the Ito table:
   print copyIto()
      table(A = dA ,A = dA ,t= dt,X= dX)
             2    2  1    1

The d function can extract these symbols:
   [d A[i] for i in 1..2]
       [dA ,dA ]
          1   2

========================================================================
BinaryExpansion examples
========================================================================

All rational numbers have repeating binary expansions.  Operations to
access the individual bits of a binary expansion can be obtained by
converting the value to RadixExpansion(2).  More examples of
expansions are available with

The expansion (of type BinaryExpansion) of a rational number is
returned by the binary operation.

  r := binary(22/7)
      ---
   11.001
                      Type: BinaryExpansion

Arithmetic is exact.

  r + binary(6/7)
   100
                      Type: BinaryExpansion

The period of the expansion can be short or long.

  [binary(1/i) for i in 102..106]
      --------
   [0.00000101,
      ----------------------------------------------------
    0.0000001001111100010001011001011110011100100101010001,
         ------------    ------------
    0.000000100111011, 0.000000100111,
       ---------------------------------------------------
    0.0000001001101010010000111001111101100101010111100011]
                      Type: List BinaryExpansion

or very long.
```

```

```
)abbrev domain BINFILE BinaryFile
++ Author: Barry M. Trager
++ Date Created: 1993
++ Description:
++ This domain provides an implementation of binary files. Data is
++ accessed one byte at a time as a small integer.

BinaryFile: Cat == Def where

    Cat == FileCategory(FileName, SingleInteger) with
        readIfCan_!: % -> Union(SingleInteger, "failed")
            ++ readIfCan!(f) returns a value from the file f, if possible.
            ++ If f is not open for reading, or if f is at the end of file
            ++ then \spad{"failed"} is the result.

--      "#": % -> SingleInteger
--          ++ #(f) returns the length of the file f in bytes.

        position: % -> SingleInteger
            ++ position(f) returns the current byte-position in the file f.

        position_!: (%, SingleInteger) -> SingleInteger
            ++ position!(f, i) sets the current byte-position to i.
```

```

====================================================================
BinarySearchTree examples
====================================================================

BinarySearchTree(R) is the domain of binary trees with elements of
type R, ordered across the nodes of the tree.  A non-empty binary
search tree has a value of type R, and right and left binary search
subtrees.  If a subtree is empty, it is displayed as a period (".").

Define a list of values to be placed across the tree.  The resulting
tree has 8 at the root; all other elements are in the left subtree.

  lv := [8,3,5,4,6,2,1,5,7]
   [8, 3, 5, 4, 6, 2, 1, 5, 7]
                      Type: List PositiveInteger

A convenient way to create a binary search tree is to apply the
operation binarySearchTree to a list of elements.

  t := binarySearchTree lv
   [[[1, 2, .], 3, [4, 5, [5, 6, 7]]], 8, .]
                      Type: BinarySearchTree PositiveInteger

Another approach is to first create an empty binary search tree of integers.

  emptybst := empty()$BSTREE(INT)
   []
                      Type: BinarySearchTree Integer

Insert the value 8.  This establishes 8 as the root of the binary
search tree.  Values inserted later that are less than 8 get stored in
the left subtree, others in the right subtree.

  t1 := insert!(8,emptybst)
   8
                      Type: BinarySearchTree Integer

Insert the value 3. This number becomes the root of the left subtree
of t1.  For optimal retrieval, it is thus important to insert the
middle elements first.

  insert!(3,t1)
   [3, 8, .]
                      Type: BinarySearchTree Integer

We go back to the original tree t.  The leaves of the binary search
tree are those which have empty left and right subtrees.
```

```
  leaves t
   [1, 4, 5, 7]
                      Type: List PositiveInteger
```

The operation split(k,t) returns a record containing the two subtrees:
one with all elements "less" than k, another with elements "greater"
than k.

```
  split(3,t)
   [less=[1, 2, .], greater=[[., 3, [4, 5, [5, 6, 7]]], 8, .]]
              Type: Record(less: BinarySearchTree PositiveInteger,greater:
                           BinarySearchTree PositiveInteger)
```

Define insertRoot to insert new elements by creating a new node.

```
  insertRoot: (INT,BSTREE INT) -> BSTREE INT
                      Type: Void
```

The new node puts the inserted value between its "less" tree and
"greater" tree.

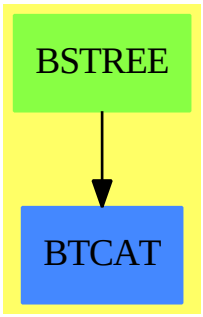
```
  insertRoot(x, t) ==
    a := split(x, t)
    node(a.less, x, a.greater)
                      Type: Void
```

Function buildFromRoot builds a binary search tree from a list
of elements ls and the empty tree emptybst.

```
  buildFromRoot ls == reduce(insertRoot,ls,emptybst)
                      Type: Void
```

Apply this to the reverse of the list lv.

```
  rt := buildFromRoot reverse lv
   [[[1, 2, . ], 3, [4, 5, [5, 6, 7]]], 8, .]
                      Type: BinarySearchTree Integer
```



Have Axiom check that these are equal.

```
  (t = rt)@Boolean
   true
                      Type: Boolean
```

— CardinalNumber.help —

```
=====================================================================
CardinalNumber examples
=====================================================================
```

```
The CardinalNumber domain can be used for values indicating the
cardinality of sets, both finite and infinite.  For example, the
dimension operation in the category VectorSpace returns a cardinal
number.

The non-negative integers have a natural construction as cardinals

  0 = #{ }, 1 = {0}, 2 = {0, 1}, ..., n = {i | 0 <= i < n}.

The fact that 0 acts as a zero for the multiplication of cardinals is
equivalent to the axiom of choice.

Cardinal numbers can be created by conversion from non-negative integers.

  c0 := 0 :: CardinalNumber
   0
                      Type: CardinalNumber

  c1 := 1 :: CardinalNumber
   1
                      Type: CardinalNumber

  c2 := 2 :: CardinalNumber
   2
                      Type: CardinalNumber

  c3 := 3 :: CardinalNumber
   3
                      Type: CardinalNumber

They can also be obtained as the named cardinal Aleph(n).

  A0 := Aleph 0
   Aleph(0)
                      Type: CardinalNumber

  A1 := Aleph 1
   Aleph(1)
                      Type: CardinalNumber

The finite? operation tests whether a value is a finite cardinal, that
is, a non-negative integer.

  finite? c2
   true
                      Type: Boolean

  finite? A0
   false
                      Type: Boolean
```

```
Similarly, the countable?  operation determines whether a value is a
countable cardinal, that is, finite or Aleph(0).

  countable? c2
   true
                      Type: Boolean

  countable? A0
   true
                      Type: Boolean

  countable? A1
   false
                      Type: Boolean

Arithmetic operations are defined on cardinal numbers as follows:
If x = #X  and y = #Y then

  x+y  = #(X+Y) cardinality of the disjoint union
  x-y  = #(X-Y) cardinality of the relative complement
  x*y  = #(X*Y) cardinality of the Cartesian product
  x**y = #(X**Y) cardinality of the set of maps from Y to X

Here are some arithmetic examples.

  [c2 + c2, c2 + A1]
   [4, Aleph(1)]
                      Type: List CardinalNumber

  [c0*c2, c1*c2, c2*c2, c0*A1, c1*A1, c2*A1, A0*A1]
   [0, 2, 4, 0, Aleph(1), Aleph(1), Aleph(1)]
                      Type: List CardinalNumber

  [c2**c0, c2**c1, c2**c2, A1**c0, A1**c1, A1**c2]
   [1, 2, 4, 1, Aleph(1), Aleph(1)]
                      Type: List CardinalNumber

Subtraction is a partial operation: it is not defined when subtracting
a larger cardinal from a smaller one, nor when subtracting two equal
infinite cardinals.

  [c2-c1, c2-c2, c2-c3, A1-c2, A1-A0, A1-A1]
   [1, 0, "failed", Aleph(1), Aleph(1), "failed"]
                      Type: List Union(CardinalNumber,"failed")

The generalized continuum hypothesis asserts that

  2**Aleph i = Aleph(i+1)
```

```
and is independent of the axioms of set theory.

(reference: Goedel, The consistency of the continuum hypothesis,
Ann. Math. Studies, Princeton Univ. Press, 1940.)

The CardinalNumber domain provides an operation to assert whether the
hypothesis is to be assumed.

  generalizedContinuumHypothesisAssumed true
   true
                      Type: Boolean

When the generalized continuum hypothesis is assumed, exponentiation
to a transfinite power is allowed.

  [c0**A0, c1**A0, c2**A0, A0**A0, A0**A1, A1**A0, A1**A1]
   [0, 1, Aleph(1), Aleph(1), Aleph(2), Aleph(1), Aleph(2)]
                      Type: List CardinalNumber

Three commonly encountered cardinal numbers are

  a = #Z countable infinity
  c = #R the continuum
  f = #{g| g: [0,1] -> R}

In this domain, these values are obtained under the generalized
continuum hypothesis in this way.

  a := Aleph 0
   Aleph(0)
                      Type: CardinalNumber

  c := 2**a
   Aleph(1)
                      Type: CardinalNumber

  f := 2**c
   Aleph(2)
                      Type: CardinalNumber

)abbrev domain CARD CardinalNumber
++ Author: S.M. Watt
++ Date Created: June 1986
++ Date Last Updated: May 1990
++ References:
++   Goedel, "The consistency of the continuum hypothesis",
++   Ann. Math. Studies, Princeton Univ. Press, 1940
++ Description:
++ Members of the domain CardinalNumber are values indicating the
++ cardinality of sets, both finite and infinite.  Arithmetic operations
++ are defined on cardinal numbers as follows.
++
++ If \spad{x = #X}  and  \spad{y = #Y} then\br
++ \tab{5}\spad{x+y  = #(X+Y)} \tab{5}disjoint union\br
++ \tab{5}\spad{x-y  = #(X-Y)} \tab{5}relative complement\br
```

```
++ \tab{5}\spad{x*y  = #(X*Y)} \tab{5}cartesian product\br
++ \tab{5}\spad{x**y = #(X**Y)} \tab{4}\spad{X**Y = g| g:Y->X}
++
++ The non-negative integers have a natural construction as cardinals\br
++ \spad{0 = #\{\}}, \spad{1 = \{0\}},
++ \spad{2 = \{0, 1\}}, ..., \spad{n = \{i| 0 <= i < n\}}.
++
++ That \spad{0} acts as a zero for the multiplication of cardinals is
++ equivalent to the axiom of choice.
++
++ The generalized continuum hypothesis asserts \br
++ \spad{2**Aleph i = Aleph(i+1)}
++ and is independent of the axioms of set theory [Goedel 1940].
++
++ Three commonly encountered cardinal numbers are\br
++ \tab{5}\spad{a = #Z} \tab{5}countable infinity\br
++ \tab{5}\spad{c = #R} \tab{5}the continuum\br
++ \tab{5}\spad{f = # g | g:[0,1]->R\}
++
++ In this domain, these values are obtained using\br
++ \tab{5}\spad{a := Aleph 0}, \spad{c := 2**a}, \spad{f := 2**c}.

==========================================================================
CartesianTensor examples
==========================================================================

CartesianTensor(i0,dim,R) provides Cartesian tensors with components
belonging to a commutative ring R.  Tensors can be described as a
generalization of vectors and matrices.  This gives a concise tensor
algebra for multilinear objects supported by the CartesianTensor
domain.  You can form the inner or outer product of any two tensors
and you can add or subtract tensors with the same number of components.
Additionally, various forms of traces and transpositions are useful.

The CartesianTensor constructor allows you to specify the minimum
index for subscripting.  In what follows we discuss in detail how to
manipulate tensors.

Here we construct the domain of Cartesian tensors of dimension 2 over the
integers, with indices starting at 1.

  CT := CARTEN(i0 := 1, 2, Integer)
   CartesianTensor(1,2,Integer)
                      Type: Domain

==========================================================================
Forming tensors
==========================================================================

Scalars can be converted to tensors of rank zero.

  t0: CT := 8
   8
                      Type: CartesianTensor(1,2,Integer)

  rank t0
   0
                      Type: NonNegativeInteger

Vectors (mathematical direct products, rather than one dimensional array
structures) can be converted to tensors of rank one.

  v: DirectProduct(2, Integer) := directProduct [3,4]
   [3, 4]
```

```
                    Type: DirectProduct(2,Integer)

  Tv: CT := v
   [3, 4]
                    Type: CartesianTensor(1,2,Integer)
```

Matrices can be converted to tensors of rank two.

```
  m: SquareMatrix(2, Integer) := matrix [ [1,2],[4,5] ]
   +1  2+
   |    |
   +4  5+
                    Type: SquareMatrix(2,Integer)

  Tm: CT := m
   +1  2+
   |    |
   +4  5+
                    Type: CartesianTensor(1,2,Integer)

  n: SquareMatrix(2, Integer) := matrix [ [2,3],[0,1] ]
   +2  3+
   |    |
   +0  1+
                    Type: SquareMatrix(2,Integer)

  Tn: CT := n
   +2  3+
   |    |
   +0  1+
                    Type: CartesianTensor(1,2,Integer)
```

In general, a tensor of rank k can be formed by making a list of
rank k-1 tensors or, alternatively, a k-deep nested list of lists.

```
  t1: CT := [2, 3]
   [2, 3]
                    Type: CartesianTensor(1,2,Integer)

  rank t1
   1
                    Type: PositiveInteger

  t2: CT := [t1, t1]
   +2  3+
   |    |
   +2  3+
                    Type: CartesianTensor(1,2,Integer)

  t3: CT := [t2, t2]
```

```
   +2  3+ +2  3+
  [|    |,|    |]
   +2  3+ +2  3+
                    Type: CartesianTensor(1,2,Integer)

  tt: CT := [t3, t3]; tt := [tt, tt]
    ++2  3+  +2  3++ ++2  3+  +2  3++
    ||    |  |    || ||    |  |    ||
    |+2  3+  +2  3+| |+2  3+  +2  3+|
   [|              |,|              |]
    |+2  3+  +2  3+| |+2  3+  +2  3+|
    ||    |  |    || ||    |  |    ||
    ++2  3+  +2  3++ ++2  3+  +2  3++
                    Type: CartesianTensor(1,2,Integer)

  rank tt
   5
                    Type: PositiveInteger
```

```
========================================================================
Multiplication
========================================================================

Given two tensors of rank k1 and k2, the outer product forms a new
tensor of rank k1+k2. Here

  Tmn(i,j,k,l) = Tm(i,j)Tn(k,l)

  Tmn := product(Tm, Tn)
    ++2  3+    +4  6+ +
    ||    |    |    | |
    |+0  1+    +0  2+ |
    |                 |
    |+8  12+  +10  15+|
    ||     |  |      ||
    ++0  4 +  +0   5 ++
                    Type: CartesianTensor(1,2,Integer)

The inner product (contract) forms a tensor of rank k1+k2-2.  This
product generalizes the vector dot product and matrix-vector product
by summing component products along two indices.

Here we sum along the second index of Tm and the first index of Tv. Here

 Tmv = sum {j=1..dim} Tm(i,j) Tv(j)

 Tmv := contract(Tm,2,Tv,1)
   [11,32]
                    Type: CartesianTensor(1,2,Integer)
```

```
The multiplication operator * is scalar multiplication or an inner
product depending on the ranks of the arguments.

If either argument is rank zero it is treated as scalar multiplication.
Otherwise, a*b is the inner product summing the last index of a with the
first index of b.

  Tm*Tv
   [11,32]
                    Type: CartesianTensor(1,2,Integer)

This definition is consistent with the inner product on matrices
and vectors.

  Tmv = m * v
   [11,32] = [11,32]
                    Type: Equation CartesianTensor(1,2,Integer)

========================================================================
Selecting Components
========================================================================

For tensors of low rank (that is, four or less), components can be selected
by applying the tensor to its indices.

  t0()
   8
                    Type: PositiveInteger

  t1(1+1)
   3
                    Type: PositiveInteger

  t2(2,1)
   2
                    Type: PositiveInteger

  t3(2,1,2)
    3
                    Type: PositiveInteger

  Tmn(2,1,2,1)
    0
                    Type: NonNegativeInteger

A general indexing mechanism is provided for a list of indices.

  t0[]
    8
```

```
                    Type: PositiveInteger

  t1[2]
    3
                    Type: PositiveInteger

  t2[2,1]
    2
                    Type: PositiveInteger

The general mechanism works for tensors of arbitrary rank, but is
somewhat less efficient since the intermediate index list must be created.

  t3[2,1,2]
    3
                    Type: PositiveInteger

  Tmn[2,1,2,1]
    0
                    Type: NonNegativeInteger

========================================================================
Contraction
========================================================================

A "contraction" between two tensors is an inner product, as we have
seen above.  You can also contract a pair of indices of a single
tensor.  This corresponds to a "trace" in linear algebra.  The
expression contract(t,k1,k2) forms a new tensor by summing the
diagonal given by indices in position k1 and k2.

This is the tensor given by
  xTmn = sum{k=1..dim} Tmn(k,k,i,j)

  cTmn := contract(Tmn,1,2)
    +12  18+
    |      |
    +0   6 +
                        Type: CartesianTensor(1,2,Integer)

Since Tmn is the outer product of matrix m and matrix n, the above is
equivalent to this.

  trace(m) * n
    +12  18+
    |      |
    +0   6 +
                        Type: SquareMatrix(2,Integer)

In this and the next few examples, we show all possible contractions
```

```
of Tmn and their matrix algebra equivalents.

  contract(Tmn,1,2) = trace(m) * n
   +12  18+  +12  18+
   |      |= |      |
   +0   6 +  +0   6 +
                          Type: Equation CartesianTensor(1,2,Integer)

  contract(Tmn,1,3) = transpose(m) * n
   +2  7 +  +2  7 +
   |     |= |     |
   +4  11+  +4  11+
                          Type: Equation CartesianTensor(1,2,Integer)

  contract(Tmn,1,4) = transpose(m) * transpose(n)
   +14  4+  +14  4+
   |     |= |     |
   +19  5+  +19  5+
                          Type: Equation CartesianTensor(1,2,Integer)

  contract(Tmn,2,3) = m * n
   +2  5 +  +2  5 +
   |     |= |     |
   +8  17+  +8  17+
                          Type: Equation CartesianTensor(1,2,Integer)

  contract(Tmn,2,4) = m * transpose(n)
   +8   2+  +8   2+
   |     |= |     |
   +23  5+  +23  5+
                          Type: Equation CartesianTensor(1,2,Integer)

  contract(Tmn,3,4) = trace(n) * m
   +3   6 +  +3   6 +
   |      |= |      |
   +12  15+  +12  15+
                          Type: Equation CartesianTensor(1,2,Integer)

========================================================================
Transpositions
========================================================================

You can exchange any desired pair of indices using the transpose
operation.

Here the indices in positions one and three are exchanged, that is,
  tTmn(i,j,k,l) = Tmn(k,j,i,l)

  tTmn := transpose(Tmn,1,3)
   ++2  3 +  +4   6 ++
```

```
   ||     |  |      ||
   |+8  12+  +10  15+|
   |                 |
   |+0  1+    +0  2+ |
   ||    |    |    | |
   ++0  4+    +0  5+ +
                            Type: CartesianTensor(1,2,Integer)
```

If no indices are specified, the first and last index are exchanged.

```
  transpose Tmn
   ++2  8+   +4  10++
   ||    |   |     ||
   |+0  0+   +0  0 +|
   |               |
   |+3  12+  +6  15+|
   ||     |  |     ||
   ++1  4 +  +2  5 ++
                            Type: CartesianTensor(1,2,Integer)
```

This is consistent with the matrix transpose.

```
  transpose Tm = transpose m
   +1  4+  +1  4+
   |    |= |    |
   +2  5+  +2  5+
                            Type: Equation CartesianTensor(1,2,Integer)
```

If a more complicated reordering of the indices is required, then the reindex operation can be used. This operation allows the indices to be arbitrarily permuted.

```
  rTmn(i,j,k,l) = Tmn(i,l,j,k)

  rTmn := reindex(Tmn, [1,4,2,3])
   ++2  0+   +3  1+ +
   ||    |   |    | |
   |+4  0+   +6  2+ |
   |               |
   |+8   0+  +12  4+|
   ||     |  |     ||
   ++10  0+  +15  5++
                             Type: CartesianTensor(1,2,Integer)
```

```
========================================================================
Arithmetic
========================================================================
```

Tensors of equal rank can be added or subtracted so arithmetic

expressions can be used to produce new tensors.

```
  tt := transpose(Tm)*Tn - Tn*transpose(Tm)
   +- 6  - 16+
   |         |
   + 2    6  +
                              Type: CartesianTensor(1,2,Integer)

  Tv*(tt+Tn)
   [- 4,- 11]
                              Type: CartesianTensor(1,2,Integer)

  reindex(product(Tn,Tn),[4,3,2,1])+3*Tn*product(Tm,Tm)
   ++46   84 +  +57   114++
   ||        |  |        ||
   |+174  212+  +228  285+|
   |                      |
   | +18  24+    +17  30+ |
   | |      |    |      | |
   + +57  63+    +63  76+ +
                              Type: CartesianTensor(1,2,Integer)
```

```
======================================================================
Specific Tensors
======================================================================
```

Two specific tensors have properties which depend only on the dimension.

The Kronecker delta satisfies

```
             +-              -+
             |   1  if i  = j |
delta(i,j) = |                |
             |   0  if i ^= j |
             +-              -+

  delta:  CT := kroneckerDelta()
   +1  0+
   |    |
   +0  1+
                              Type: CartesianTensor(1,2,Integer)
```

This can be used to reindex via contraction.

```
  contract(Tmn, 2, delta, 1) = reindex(Tmn, [1,3,4,2])
   + +2  4+   +0  0++  + +2  4+   +0  0++
   | |    |   |    ||  | |    |   |    ||
   | +3  6+   +1  2+|  | +3  6+   +1  2+|
```

```
   |                |= |                |
   |+8   10+  +0  0+|  |+8   10+  +0  0+|
   ||      |  |    ||  ||      |  |    ||
   ++12  15+  +4  5++  ++12  15+  +4  5++
                              Type: Equation CartesianTensor(1,2,Integer)
```

The Levi Civita symbol determines the sign of a permutation of indices.

```
  epsilon:CT := leviCivitaSymbol()
   + 0   1+
   |      |
   +- 1  0+
                               Type: CartesianTensor(1,2,Integer)
```

Here we have:

```
  epsilon(i1,...,idim)
     = +1  if i1,...,idim is an even permutation of i0,...,i0+dim-1
     = -1  if i1,...,idim is an  odd permutation of i0,...,i0+dim-1
     =  0  if i1,...,idim is not   a permutation of i0,...,i0+dim-1
```

This property can be used to form determinants.

```
  contract(epsilon*Tm*epsilon, 1,2) = 2 * determinant m
   - 6= - 6
                              Type: Equation CartesianTensor(1,2,Integer)
```

```
========================================================================
Properties of the CartesianTensor domain
========================================================================
```

GradedModule(R,E) denotes "E-graded R-module", that is, a collection of R-modules indexed by an abelian monoid E. An element g of G[s] for some specific s in E is said to be an element of G with degree s. Sums are defined in each module G[s] so two elements of G can be added if they have the same degree. Morphisms can be defined and composed by degree to give the mathematical category of graded modules.

GradedAlgebra(R,E) denotes "E-graded R-algebra". A graded algebra is a graded module together with a degree preserving R-bilinear map, called the product.

```
  degree(product(a,b))    = degree(a) + degree(b)

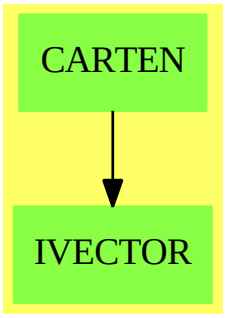
  product(r*a,b)          = product(a,r*b) = r*product(a,b)
  product(a1+a2,b)        = product(a1,b) + product(a2,b)
  product(a,b1+b2)        = product(a,b1) + product(a,b2)
  product(a,product(b,c)) = product(product(a,b),c)
```

```
The domain CartesianTensor(i0, dim, R) belongs to the category
GradedAlgebra(R, NonNegativeInteger).  The non-negative integer degree
is the tensor rank and the graded algebra product is the tensor outer
product.  The graded module addition captures the notion that only
tensors of equal rank can be added.

If V is a vector space of dimension dim over R, then the tensor module
T[k](V) is defined as

 T[0](V) = R
  T[k](V) = T[k-1](V) * V

where * denotes the R-module tensor product. CartesianTensor(i0,dim,R)
is the graded algebra in which the degree k module is T[k](V).



========================================================================
Tensor Calculus
========================================================================

It should be noted here that often tensors are used in the context of
tensor-valued manifold maps.  This leads to the notion of covariant
and contravariant bases with tensor component functions transforming
in specific ways under a change of coordinates on the manifold.  This
is no more directly supported by the CartesianTensor domain than it is
by the Vector domain.  However, it is possible to have the components
implicitly represent component maps by choosing a polynomial or
expression type for the components.  In this case, it is up to the
user to satisfy any constraints which arise on the basis of this
interpretation.

— domain CARTEN CartesianTensor —

```
)abbrev domain CARTEN CartesianTensor
++ Author: Stephen M. Watt
++ Date Created: December 1986
++ Date Last Updated: May 15, 1991
++ Description:
++ CartesianTensor(minix,dim,R) provides Cartesian tensors with
++ components belonging to a commutative ring R.  These tensors
++ can have any number of indices.  Each index takes values from
++ \spad{minix} to \spad{minix + dim - 1}.

CartesianTensor(minix, dim, R): Exports == Implementation where
    NNI ==> NonNegativeInteger
    I   ==> Integer
    DP  ==> DirectProduct
    SM  ==> SquareMatrix

    minix: Integer
    dim: NNI

=====================================================================
Character examples
=====================================================================

The members of the domain Character are values representing letters,
numerals and other text elements.

Characters can be obtained using String notation.

  chars := [char "a", char "A", char "X", char "8", char "+"]
   [a,A,X,8,+]
                      Type: List Character

Certain characters are available by name. This is the blank character.

  space()

                      Type: Character

This is the quote that is used in strings.

  quote()
   "
                      Type: Character

This is the escape character that allows quotes and other characters
within strings.

  escape()
   -
                      Type: Character

Characters are represented as integers in a machine-dependent way.
The integer value can be obtained using the ord operation.  It is
always true that char(ord c) = c and ord(char i) = i, provided that i
is in the range 0..size()$Character-1.

  [ord c for c in chars]
   [97,65,88,56,43]
                      Type: List Integer
```

```
The lowerCase operation converts an upper case letter to the
corresponding lower case letter.  If the argument is not an upper case
letter, then it is returned unchanged.

  [upperCase c for c in chars]
    [A,A,X,8,+]
                      Type: List Character

The upperCase operation converts lower case letters to upper case.

  [lowerCase c for c in chars]
   [a,a,x,8,+]
                      Type: List Character

A number of tests are available to determine whether characters
belong to certain families.

  [alphabetic? c for c in chars]
   [true,true,true,false,false]
                      Type: List Boolean

  [upperCase? c for c in chars]
   [false,true,true,false,false]
                      Type: List Boolean

  [lowerCase? c for c in chars]
    [true,false,false,false,false]
                      Type: List Boolean

  [digit? c for c in chars]
   [false,false,false,true,false]
                      Type: List Boolean

  [hexDigit? c for c in chars]
   [true,true,false,true,false]
                      Type: List Boolean

  [alphanumeric? c for c in chars]
   [true,true,true,true,false]
                      Type: List Boolean

— domain CHAR Character —

```
)abbrev domain CHAR Character
++ Author: Stephen M. Watt
++ Date Created: July 1986
++ Date Last Updated: June 20, 1991
++ Description:
++ This domain provides the basic character data type.

Character: OrderedFinite() with
  ord: % -> Integer
    ++ord(c) provides an integral code corresponding to the
    ++character c.  It is always true that \spad{char ord c = c}.
    ++
    ++X chars := [char "a", char "A", char "X", char "8", char "+"]
    ++X [ord c for c in chars]
  char: Integer  -> %
    ++char(i) provides a character corresponding to the integer
    ++code i. It is always true that \spad{ord char i = i}.
    ++
    ++X [char c for c in [97,65,88,56,43]]
  char: String   -> %
```

```
  ++char(s) provides a character from a string s of length one.
  ++
  ++X [char c for c in ["a","A","X","8","+"]]
space: () -> %
  ++space() provides the blank character.
  ++
  ++X space()
quote: () -> %
  ++quote() provides the string quote character, \spad{"}.
  ++
  ++X quote()
escape: () -> %
  ++escape() provides the escape character, \spad{_}, which
  ++is used to allow quotes and other characters within strings.
  ++
  ++X escape()
upperCase: % -> %
  ++upperCase(c) converts a lower case letter to the corresponding
  ++upper case letter.  If c is not a lower case letter, then
  ++it is returned unchanged.
  ++
  ++X chars := [char "a", char "A", char "X", char "8", char "+"]
  ++X [upperCase c for c in chars]
lowerCase: % -> %
  ++lowerCase(c) converts an upper case letter to the corresponding
  ++lower case letter.  If c is not an upper case letter, then
  ++it is returned unchanged.
  ++
  ++X chars := [char "a", char "A", char "X", char "8", char "+"]
  ++X [lowerCase c for c in chars]
digit?: % -> Boolean
  ++digit?(c) tests if c is a digit character, for example, one of 0..9.
  ++
  ++X chars := [char "a", char "A", char "X", char "8", char "+"]
  ++X [digit? c for c in chars]
hexDigit?: % -> Boolean
  ++hexDigit?(c) tests if c is a hexadecimal numeral,
  ++for example, one of 0..9, a..f or A..F.
  ++
  ++X chars := [char "a", char "A", char "X", char "8", char "+"]
  ++X [hexDigit? c for c in chars]
alphabetic?: % -> Boolean

=====================================================================
CharacterClass examples
=====================================================================

The CharacterClass domain allows classes of characters to be defined
and manipulated efficiently.

Character classes can be created by giving either a string or a list
of characters.

  cl1:=charClass[char "a",char "e",char "i",char "o",char "u",char "y"]
   "aeiouy"
                     Type: CharacterClass

  cl2 := charClass "bcdfghjklmnpqrstvwxyz"
   "bcdfghjklmnpqrstvwxyz"
                     Type: CharacterClass

A number of character classes are predefined for convenience.

  digit()
   "0123456789"
                     Type: CharacterClass

  hexDigit()
   "0123456789ABCDEFabcdef"
                     Type: CharacterClass
```

```
  upperCase()
   "ABCDEFGHIJKLMNOPQRSTUVWXYZ"
                      Type: CharacterClass

  lowerCase()
   "abcdefghijklmnopqrstuvwxyz"
                      Type: CharacterClass

  alphabetic()
   "ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz"
                      Type: CharacterClass

  alphanumeric()
   "0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz"
                      Type: CharacterClass
```

You can quickly test whether a character belongs to a class.

```
  member?(char "a", cl1)
   true
                      Type: Boolean

  member?(char "a", cl2)
   false
                      Type: Boolean
```

Classes have the usual set operations because the CharacterClass domain belongs to the category FiniteSetAggregate(Character).

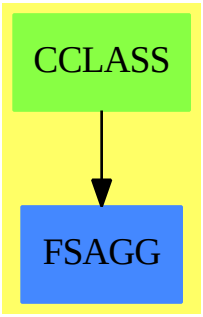
```
  intersect(cl1, cl2)
   "y"
                      Type: CharacterClass

  union(cl1,cl2)
   "abcdefghijklmnopqrstuvwxyz"
                      Type: CharacterClass

  difference(cl1,cl2)
   "aeiou"
                      Type: CharacterClass

  intersect(complement(cl1),cl2)
   "bcdfghjklmnpqrstvwxz"
                      Type: CharacterClass
```

You can modify character classes by adding or removing characters.



```
  insert!(char "a", cl2)
   "abcdfghjklmnpqrstvwxyz"
                      Type: CharacterClass
```

```
  remove!(char "b", cl2)
   "acdfghjklmnpqrstvwxyz"
                      Type: CharacterClass

)abbrev domain CCLASS CharacterClass
++ Author: Stephen M. Watt
++ Date Created: July 1986
++ Date Last Updated: June 20, 1991
++ Description:
++ This domain allows classes of characters to be defined and manipulated
++ efficiently.

CharacterClass: Join(SetCategory, ConvertibleTo String,
  FiniteSetAggregate Character, ConvertibleTo List Character) with
        charClass: String -> %
          ++ charClass(s) creates a character class which contains
          ++ exactly the characters given in the string s.
        charClass: List Character -> %
          ++ charClass(l) creates a character class which contains
          ++ exactly the characters given in the list l.
        digit: constant -> %
          ++ digit() returns the class of all characters
          ++ for which digit? is true.
        hexDigit: constant -> %
          ++ hexDigit() returns the class of all characters for which
          ++ hexDigit? is true.
        upperCase: constant -> %
          ++ upperCase() returns the class of all characters for which
          ++ upperCase? is true.
        lowerCase:  constant -> %
          ++ lowerCase() returns the class of all characters for which
          ++ lowerCase? is true.
        alphabetic  :  constant -> %
          ++ alphabetic() returns the class of all characters for which
          ++ alphabetic? is true.
```

```
    alphanumeric:  constant -> %
      ++ alphanumeric() returns the class of all characters for which
      ++ alphanumeric? is true.

domain CLIF CliffordAlgebra[?, ?]

Vector (linear) spaces

This information is originally from Paul Leopardi's presentation on the *Introduction to Clifford Algebras* and is included here as an outline with his permission. Further details are based on the book by Doran and Lasenby called *Geometric Algebra for Physicists*.

Consider the various kinds of products that can occur between vectors. There are scalar and vector products from 3D geometry. There are the complex and quaterion products. There is also the *outer* or *exterior* product.

Vector addition commutes:

$$a + b = b + a$$

Vector addtion is associative:

$$a + (b + c) = (a + b) + c$$

The identity vector exists:

$$a + 0 = a$$

Every vector has an inverse:

$$a + (-a) = 0$$

If we consider vectors to be directed line segments, thus establishing a geometric meaning for a vector, then each of these properties has a geometric meaning.

A multiplication operator exists between scalars and vectors with the properties:

$$\lambda(a + b) = \lambda a + \lambda b$$

$$(\lambda + \mu)a = \lambda a + \mu a$$

$$(\lambda\mu)a = \lambda(\mu a)$$

$$\text{If } 1\lambda = \lambda \text{ for all scalars } \lambda \text{ then } 1a = a \text{ for all vectors } a$$

These properties completely define a vector (linear) space. The + operation for scalar arithmetic is not the same as the + operation for vectors.

Definition: Isomorphic The vector space A is isomorphic to the vector space B if their exists a one-to-one correspondence between their elements which preserves sums and there is a one-to-one correspondence between the scalars which preserves sums and products.

Definition: Subspace Vector space B is a subspace of vector space A if all of the elements of B are contained in A and they share the same scalars.

Definition: Linear Combination Given vectors $a_1, \ldots, a_n$ the vector b is a linear combination of the vectors if we can find scalars λ_i such that

$$b = \lambda_1 a_1 + \ldots + \lambda_n a_n = \sum_{k=1}^{n} \lambda_i a_i$$

Definition: Linearly Independent If there exists scalars λ_i such that

$$\lambda_1 a_1 + \ldots + \lambda_n a_n = 0$$

and at least one of the λ_i is not zero then the vectors $a_1, \ldots, a_n$ are linearly dependent. If no such scalars exist then the vectors are linearly independent.

Definition: Span If every vector can be written as a linear combination of a fixed set of vectors $a_1, \ldots, a_n$ then this set of vectors is said to span the vector space.

Definition: Basis If a set of vectors $a_1, \ldots, a_n$ is linearly independent and spans a vector space A then the vectors form a basis for A.

Definition: Dimension The dimension of a vector space is the number of basis elements, which is unique since all bases of a vector space have the same number of elements.

Quadratic Forms[?]

For vector space $\mathbb{V}$ over field $\mathbb{F}$, characteristic $\neq 2$:

Map $f : \mathbb{V} \to \mathbb{F}$, with

$$f(\lambda x) = \lambda^2 f(x), \forall \lambda \in \mathbb{F}, x \in \mathbb{V}$$

$f(x) = b(x, x)$, where

$$b : \mathbb{V} \text{ x } \mathbb{V} \to \mathbb{F} \text{ , given by}$$

$$b(x, y) := \frac{1}{2}(f(x + y) - f(x) = f(y))$$

is a symmetric bilinear form

Quadratic spaces, Clifford Maps[?, ?]

A quadratic space is the pair($\mathbb{V}$,f), where f is a quadratic form on $\mathbb{V}$

A Clifford map is a vector space homomorphism

$$\rho : \mathbb{V} \to \mathbb{A}$$

where $\mathbb{A}$ is an associated algebra, and

$$(\rho v)^2 = f(v), \quad \forall v \in \mathbb{V}$$

Universal Clifford algebras[?]

The *universal Clifford algebra* $Cl(f)$ for the quadratic space $(\mathbb{V}, f)$ is the algebra generated by the image of the Clifford map ϕ_f such that $Cl(f)$ is the universal initial object such that $\forall$ suitable algebra $\mathbb{A}$ with Clifford map $\phi_{\mathbb{A}} \exists$ a homomorphism

$$P_{\mathbb{A}} : Cl(f) \to \mathbb{A}$$

$$\rho_{\mathbb{A}} = P_{\mathbb{A}} \circ \rho_f$$

Real Clifford algebras $\mathbb{R}_{p,q}$[?]

The real quadratic space $\mathbb{R}^{p,q}$ is $\mathbb{R}^{p+q}$ with

$$\phi(x) := -\sum_{k:=-q}^{-1} x_k^2 + \sum_{k=1}^{p} x_k^2$$

For each $p, q \in \mathbb{N}$, the real universal Clifford algebra for $\mathbb{R}^{p,q}$ is called $\mathbb{R}_{p,q}$

$\mathbb{R}_{p,q}$ is isomorphic to some matrix algebra over one of: $\mathbb{R}$,$\mathbb{R} \oplus \mathbb{R}$,$\mathbb{C}$, $\mathbb{H}$,$\mathbb{H} \oplus \mathbb{H}$

For example, $\mathbb{R}_{1,1} \cong \mathbb{R}(2)$

Notation for integer sets

For $S \subseteq \mathbb{Z}$, define

$$\sum_{k \in S} f_k := \sum_{k=\min\ S, k \in S}^{\max\ S} f_k$$

$$\prod_{k \in S} f_k := \prod_{k=\min\ S, k \in S}^{\max\ S} f_k$$

$$\mathbb{P}(S) := \text{ the } \textit{power set} \text{ of } S$$

For $m \leq n \in \mathbb{Z}$, define

$$\zeta(m,n) := \{m, m+1, \ldots, n-1, n\} \backslash \{0\}$$

Frames for Clifford algebras[?, ?, ?]

A *frame* is an ordered basis $(\gamma_{-q}, \ldots, \gamma_p)$ for $\mathbb{R}^{p,q}$ which puts a quadratic form into the canonical form ϕ

For $p, q \in \mathbb{N}$, embed the frame for $\mathbb{R}^{p,q}$ into $\mathbb{R}_{p,q}$ via the maps

$$\gamma : \zeta(-q,p) \to \mathbb{R}^{p,q}$$

$$\rho : \mathbb{R}^{p,q} \to \mathbb{R}_{p,q}$$

$$(\rho\gamma k)^2 = \phi\gamma k = \text{ sgn } k$$

Real frame groups[?, ?]

For $p, q \in \mathbb{N}$, define the real *frame group* $\mathbb{G}_{p,q}$ via the map

$$g : \zeta(-q,p) \to \mathbb{G}_{p,q}$$

with generators and relations

$$\langle \mu, g_k | \mu g_k = g_k \mu, \quad \mu^2 = 1,$$

$$(g_k)^2 = \begin{cases} \mu, & \text{if } k < 0 \\ 1 & \text{if } k > 0 \end{cases}$$

$$g_k g_m = \mu g_m g_k \quad \forall k \neq m \rangle$$

Canonical products[?, ?, ?]

The real frame group $\mathbb{G}_{p,q}$ has order 2^{p+q+1}

Each member w can be expressed as the canonically ordered product

$$w = \mu^a \prod_{k \in T} g_k$$

$$= \mu^a \prod_{k=-q, k\neq 0}^{p} g_k^{b_k}$$

where $T \subseteq \zeta(-q,p), a, b_k \in \{0,1\}$

Clifford algebra of frame group[?, ?, ?, ?]

For $p, q \in \mathbb{N}$ embed $\mathbb{G}_{p,q}$ into $\mathbb{R}_{p,q}$ via the map

$$\alpha \mathbb{G}_{p,q} \to \mathbb{R}_{p,q}$$

$$\alpha 1 := 1, \qquad \alpha\mu := -1$$

$$\alpha g_k := \rho\gamma_k, \qquad \alpha(gh) := (\alpha g)(\alpha h)$$

Define *basis elements* via the map

$$e : \mathbb{P}\zeta(-q,p) \to \mathbb{R}_{p,q}, \qquad e_T := \alpha \prod_{k \in T} g_k$$

Each $a \in \mathbb{R}_{p,q}$ can be expressed as

$$a = \sum_{T \subseteq \zeta(-q,p)} a_T e_T$$

Neutral matrix representations[?, ?, ?]

The *representation map* P_m and *representation matrix* R_m make the following diagram commute:

$$\begin{array}{ccc} & \text{coord} & \\ \mathbb{R}_{m,m} & \longrightarrow & \mathbb{R}^{4^m} \\ \Big| & & \Big| \\ P_m & & R_m \\ \Big| & & \Big| \\ \mathrm{V} & & \mathrm{V} \\ \mathbb{R}(2^m) & \longrightarrow & \mathbb{R}^{4^m} \\ & \text{reshape} & \end{array}$$

=====================================================================
CliffordAlgebra examples
=====================================================================
```

```
CliffordAlgebra(n,K,Q) defines a vector space of dimension 2^n over
the field K with a given quadratic form Q.  If {e1..en} is a basis for
K^n then

{ 1,
  e(i)         1 <= i <= n,
  e(i1)*e(i2)  1 <= i1 < i2 <=n,
  ...,
  e(1)*e(2)*...*e(n) }

is a basis for the Clifford algebra. The algebra is defined by the relations

  e(i)*e(i) = Q(e(i))
  e(i)*e(j) = -e(j)*e(i),  for i ^= j

Examples of Clifford Algebras are gaussians (complex numbers),
quaternions, exterior algebras and spin algebras.

========================================================================
The Complex Numbers as a Clifford Algebra
========================================================================

This is the field over which we will work, rational functions with
integer coefficients.

  K := Fraction Polynomial Integer
   Fraction Polynomial Integer
                         Type: Domain

We use this matrix for the quadratic form.

  m := matrix [ [-1] ]
   [- 1]
                         Type: Matrix Integer

We get complex arithmetic by using this domain.

  C := CliffordAlgebra(1, K, quadraticForm m)
   CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)
                         Type: Domain

Here is i, the usual square root of -1.

  i: C := e(1)
   e
    1
              Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)

Here are some examples of the arithmetic.
```

```
  x := a + b * i
   a + b e
          1
               Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)

  y := c + d * i
   c + d e
          1
               Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)

  x * y
   - b d + a c + (a d + b c)e
                            1
               Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)
```

```
========================================================================
The Quaternion Numbers as a Clifford Algebra
========================================================================

This is the field over which we will work, rational functions with
integer coefficients.

  K := Fraction Polynomial Integer
   Fraction Polynomial Integer
                       Type: Domain

We use this matrix for the quadratic form.

  m := matrix [ [-1,0],[0,-1] ]
   +- 1   0 +
   |        |
   + 0   - 1+
                       Type: Matrix Integer

The resulting domain is the quaternions.

  H  := CliffordAlgebra(2, K, quadraticForm m)
   CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)
                       Type: Domain

We use Hamilton's notation for i, j, k.

  i: H  := e(1)
   e
    1
              Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

  j: H  := e(2)
   e
```

```

             Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

  k: H  := i * j
   e e
    1 2
             Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

  x := a + b * i + c * j + d * k
   a + b e  + c e  + d e e
          1      2      1 2
             Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

  y := e + f * i + g * j + h * k
   e + f e  + g e  + h e e
          1      2      1 2
             Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

  x + y
   e + a + (f + b)e  + (g + c)e  + (h + d)e e
                  1           2           1 2
             Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

  x * y
   - d h - c g - b f + a e + (c h - d g + a f + b e)e
                                                    1
   +
     (- b h + a g + d f + c e)e  + (a h + b g - c f + d e)e e
                               2                          1 2
             Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

  y * x
   - d h - c g - b f + a e + (- c h + d g + a f + b e)e
                                                      1
   +
     (b h + a g - d f + c e)e  + (a h - b g + c f + d e)e e
                             2                          1 2
                Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

======================================================================
The Exterior Algebra on a Three Space
======================================================================

This is the field over which we will work, rational functions with
integer coefficients.

  K := Fraction Polynomial Integer
   Fraction Polynomial Integer
                Type: Domain
```

```
If we chose the three by three zero quadratic form, we obtain
the exterior algebra on e(1),e(2),e(3).

  Ext := CliffordAlgebra(3, K, quadraticForm 0)
   CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)
                  Type: Domain

This is a three dimensional vector algebra.  We define i, j, k as the
unit vectors.

  i: Ext := e(1)
   e
    1
             Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)

  j: Ext := e(2)
   e
    2
             Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)

  k: Ext := e(3)
   e
    3
             Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)

Now it is possible to do arithmetic.

  x := x1*i + x2*j + x3*k
   x1 e  + x2 e  + x3 e
       1       2       3
             Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)

  y := y1*i + y2*j + y3*k
   y1 e  + y2 e  + y3 e
       1       2       3
             Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)

  x + y
   (y1 + x1)e  + (y2 + x2)e  + (y3 + x3)e
             1             2             3
             Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)

  x * y + y * x
   0
             Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)

On an n space, a grade p form has a dual n-p form.  In particular, in
three space the dual of a grade two element identifies

  e1*e2 -> e3, e2*e3 -> e1, e3*e1 -> e2.
```

```
  dual2 a == coefficient(a,[2,3]) * i + coefficient(a,[3,1]) * j + coefficient(a,[1,2]) * k
                     Type: Void
```

The vector cross product is then given by this.

```
  dual2(x*y)
   (x2 y3 - x3 y2)e  + (- x1 y3 + x3 y1)e  + (x1 y2 - x2 y1)e
                  1                     2                  3
          Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)
```

```
======================================================================
The Dirac Spin Algebra
======================================================================
```

In this section we will work over the field of rational numbers.

```
  K := Fraction Integer
   Fraction Integer
                     Type: Domain
```

We define the quadratic form to be the Minkowski space-time metric.

```
  g := matrix [ [1,0,0,0], [0,-1,0,0], [0,0,-1,0], [0,0,0,-1] ]
   +1   0    0    0 +
   |                 |
   |0  - 1   0    0 |
   |                 |
   |0   0   - 1   0 |
   |                 |
   +0   0    0   - 1+
                     Type: Matrix Integer
```

We obtain the Dirac spin algebra used in Relativistic Quantum Field Theory.

```
  D := CliffordAlgebra(4,K, quadraticForm g)
   CliffordAlgebra(4,Fraction Integer,MATRIX)
                     Type: Domain
```

The usual notation for the basis is gamma with a superscript. For
Axiom input we will use gam(i):

```
  gam := [e(i)$D for i in 1..4]
   [e ,e ,e ,e ]
     1  2  3  4
                Type: List CliffordAlgebra(4,Fraction Integer,MATRIX)
```

There are various contraction identities of the form

```
  g(l,t)*gam(l)*gam(m)*gam(n)*gam(r)*gam(s)*gam(t) =
```

```
      2*(gam(s)gam(m)gam(n)gam(r) + gam(r)*gam(n)*gam(m)*gam(s))

where a sum over l and t is implied.

Verify this identity for particular values of m,n,r,s.

  m := 1; n:= 2; r := 3; s := 4;
                     Type: PositiveInteger

  lhs := reduce(+, [reduce(+, [ g(l,t)*gam(l)*gam(m)*gam(n)*gam(r)*gam(s)*gam(t) for l in 1..4]) for t in 1
   - 4e e e e
       1 2 3 4
                     Type: CliffordAlgebra(4,Fraction Integer,MATRIX)

  rhs := 2*(gam s * gam m*gam n*gam r + gam r*gam n*gam m*gam s)
   - 4e e e e
       1 2 3 4
                     Type: CliffordAlgebra(4,Fraction Integer,MATRIX)

— domain CLIF CliffordAlgebra —

```
)abbrev domain CLIF CliffordAlgebra
++ Author: Stephen M. Watt
++ Date Created: August 1988
++ Date Last Updated: May 17, 1991
++ Description:
++ CliffordAlgebra(n, K, Q) defines a vector space of dimension \spad{2**n}
++ over K, given a quadratic form Q on \spad{K**n}.
++
++ If \spad{e[i]}, \spad{1<=i<=n} is a basis for \spad{K**n} then
++ 1, \spad{e[i]} (\spad{1<=i<=n}), \spad{e[i1]*e[i2]}
++ (\spad{1<=i1<i2<=n}),...,\spad{e[1]*e[2]*..*e[n]}
++ is a basis for the Clifford Algebra.
++
++ The algebra is defined by the relations\br
++ \tab{5}\spad{e[i]*e[j] = -e[j]*e[i]}  (\spad{i \~~= j}),\br
++ \tab{5}\spad{e[i]*e[i] = Q(e[i])}
++
++ Examples of Clifford Algebras are: gaussians, quaternions, exterior
++ algebras and spin algebras.

=====================================================================
Complex examples
```

```
====================================================================

The Complex constructor implements complex objects over a commutative
ring R.  Typically, the ring R is Integer, Fraction Integer, Float or
DoubleFloat.  R can also be a symbolic type, like Polynomial Integer.

Complex objects are created by the complex operation.

  a := complex(4/3,5/2)
   4   5
   - + - %i
   3   2
                        Type: Complex Fraction Integer

  b := complex(4/3,-5/2)
   4   5
   - - - %i
   3   2
                        Type: Complex Fraction Integer

The standard arithmetic operations are available.

  a + b
   8
   -
   3
                        Type: Complex Fraction Integer

  a - b
   5%i
                        Type: Complex Fraction Integer

  a * b
   289
   ---
    36
                        Type: Complex Fraction Integer

If  R is a field, you can also divide the complex objects.

  a / b
     161   240
   - --- + --- %i
     289   289
                        Type: Complex Fraction Integer

We can view the last object as a fraction of complex integers.

  % :: Fraction Complex Integer
```

```
   - 15 + 8%i
   ----------
     15 + 8%i
                        Type: Fraction Complex Integer
```

The predefined macro %i is defined to be complex(0,1).

```
  3.4 + 6.7 * %i
   3.4 + 6.7 %i
                       Type: Complex Float
```

You can also compute the conjugate and norm of a complex number.

```
  conjugate a
   4   5
   - - - %i
   3   2
                       Type: Complex Fraction Integer

  norm a
   289
   ---
    36
                       Type: Fraction Integer
```

The real and imag operations are provided to extract the real and imaginary parts, respectively.

```
  real a
   4
   -
   3
                       Type: Fraction Integer

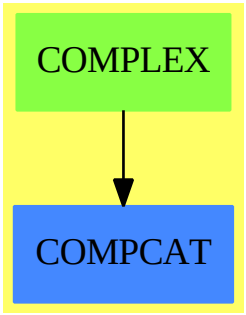
  imag a
   5
   -
   2
                       Type: Fraction Integer
```

The domain Complex Integer is also called the Gaussian integers. If R is the integers (or, more generally, a EuclideanDomain), you can compute greatest common divisors.

```
  gcd(13 - 13*%i,31 + 27*%i)
   5 + %i
                       Type: Complex Integer
```

You can also compute least common multiples.

```
  lcm(13 - 13*%i,31 + 27*%i)
   143 - 39%i
                        Type: Complex Integer



You can factor Gaussian integers.

  factor(13 - 13*%i)
   - (1 + %i)(2 + 3%i)(3 + 2%i)
                        Type: Factored Complex Integer

  factor complex(2,0)
                 2
   - %i (1 + %i)
                        Type: Factored Complex Integer

```

```
This domain creates a lisp simple array of machine doublefloats.
It provides one new function called qnew which takes an integer
that gives the array length.

NOTE: Unlike normal Axiom arrays the ComplexDoubleFloatMatrix arrays
are 0-based so the first element is 0. Axiom arrays normally
start at 1.

====================================================================
ComplexDoubleFloatVector examples
====================================================================
This domain creates a lisp simple array of machine complex doublefloats.
It provides one new function called qnew which takes an integer
that gives the array length.

NOTE: Unlike normal Axiom arrays the ComplexDoubleFloatVector arrays
are 0-based so the first element is 0. Axiom arrays normally
start at 1.

======================================================================
ContinuedFraction examples
======================================================================

Continued fractions have been a fascinating and useful tool in
mathematics for well over three hundred years.  Axiom implements
continued fractions for fractions of any Euclidean domain.  In
practice, this usually means rational numbers.  In this section we
demonstrate some of the operations available for manipulating both
finite and infinite continued fractions.

The ContinuedFraction domain is a field and therefore you can add,
subtract, multiply and divide the fractions.

The continuedFraction operation converts its fractional argument to a
continued fraction.

  c := continuedFraction(314159/100000)
        1 |     1  |     1 |     1  |     1 |     1 |     1 |
   3 + +---+ + +----+ + +---+ + +----+ + +---+ + +---+ + +---+
       | 7     | 15     | 1     | 25     | 1     | 7     | 4
                      Type: ContinuedFraction Integer

This display is a compact form of the bulkier

          3 +                 1
              -------------------------------
              7 +               1
                  ---------------------------
                  15 +            1
                       ----------------------
                       1 +          1
                           ------------------
                           25 +       1
                                ------------
                                1 +     1
                                    ---------
                                    7 +   1
                                        -----
                                          4

You can write any rational number in a similar form.  The fraction
will be finite and you can always take the "numerators" to be 1.
That is, any rational number can be written as a simple, finite
continued fraction of the form

          a(1) +           1
```

```
                        ------------------------
                        a(2) +          1
                               --------------------
                               a(3) +
                                      .
                                       .
                                        .
                                              1
                                        -------------
                                        a(n-1) +  1
                                                  ----
                                                  a(n)
```

The a(i) are called partial quotients and the operation partialQuotients creates a stream of them.

```
  partialQuotients c
   [3,7,15,1,25,1,7,4]
                        Type: Stream Integer
```

By considering more and more of the fraction, you get the convergents. For example, the first convergent is a(1), the second is a(1) + 1/a(2) and so on.

```
  convergents c
      22 333 355 9208 9563 76149 314159
   [3,--,---,---,----,----,-----,------]
       7 106 113 2931 3044 24239 100000
                         Type: Stream Fraction Integer
```

Since this is a finite continued fraction, the last convergent is the original rational number, in reduced form. The result of approximants is always an infinite stream, though it may just repeat the "last" value.

```
  approximants c
                                  ------
      22 333 355 9208 9563 76149 314159
   [3,--,---,---,----,----,-----,------]
       7 106 113 2931 3044 24239 100000
                         Type: Stream Fraction Integer
```

Inverting c only changes the partial quotients of its fraction by inserting a 0 at the beginning of the list.

```
  pq := partialQuotients(1/c)
   [0,3,7,15,1,25,1,7,4]
                         Type: Stream Integer
```

Do this to recover the original continued fraction from this list of

partial quotients. The three-argument form of the continuedFraction operation takes an element which is the whole part of the fraction, a stream of elements which are the numerators of the fraction, and a stream of elements which are the denominators of the fraction.

```
  continuedFraction(first pq,repeating [1],rest pq)
     1 |     1 |     1  |     1 |     1  |     1 |     1 |     1 |
   +---+ + +---+ + +----+ + +---+ + +----+ + +---+ + +---+ + +---+
   | 3     | 7     | 15     | 1     | 25     | 1     | 7     | 4
                        Type: ContinuedFraction Integer
```

The streams need not be finite for continuedFraction. Can you guess which irrational number has the following continued fraction? See the end of this section for the answer.

```
  z:=continuedFraction(3,repeating [1],repeating [3,6])
           1 |     1 |     1 |     1 |     1 |     1 |     1 |     1 |     1 |
     3 + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+
         | 3     | 6     | 3     | 6     | 3     | 6     | 3     | 6     | 3
   +
       1 |
     +---+ + ...
     | 6
                         Type: ContinuedFraction Integer
```

In 1737 Euler discovered the infinite continued fraction expansion

$$\frac{e-1}{2} = \cfrac{1}{1+\cfrac{1}{6+\cfrac{1}{10+\cfrac{1}{14+\ldots}}}}$$

We use this expansion to compute rational and floating point approximations of e. For this and other interesting expansions, see C. D. Olds, Continued Fractions, New Mathematical Library, (New York: Random House, 1963), pp. 134--139.}

By looking at the above expansion, we see that the whole part is 0 and the numerators are all equal to 1. This constructs the stream of denominators.

```
  dens:Stream Integer := cons(1,generate((x+->x+4),6))
   [1,6,10,14,18,22,26,30,34,38,...]
                        Type: Stream Integer
```

```
Therefore this is the continued fraction expansion for (e - 1) / 2.

  cf := continuedFraction(0,repeating [1],dens)
       1 |     1 |     1  |     1  |     1  |     1  |     1  |     1  |
     +---+ + +---+ + +----+ + +----+ + +----+ + +----+ + +----+ + +----+
     | 1     | 6     | 10     | 14     | 18     | 22     | 26     | 30
   +
       1  |     1  |
     +----+ + +----+ + ...
     | 34     | 38
                    Type: ContinuedFraction Integer

These are the rational number convergents.

  ccf := convergents cf
        6 61  860 15541 342762  8927353 268163352  9126481321
   [0,1,-,--,----,-----,------,--------,---------,----------,...]
        7 71 1001 18089 398959 10391023 312129649 10622799089
                    Type: Stream Fraction Integer

You can get rational convergents for e by multiplying by 2 and adding 1.

  eConvergents := [2*e + 1 for e in ccf]
         19 193 2721 49171 1084483 28245729 848456353 28875761731
    [1,3,--,---,----,-----,-------,--------,---------,----------,...]
          7  71 1001 18089  398959 10391023 312129649 10622799089
                    Type: Stream Fraction Integer

You can also compute the floating point approximations to these convergents.

  eConvergents :: Stream Float
   [1.0, 3.0, 2.7142857142 857142857, 2.7183098591 549295775,
    2.7182817182 817182817, 2.7182818287 356957267, 2.7182818284 585634113,
    2.7182818284 590458514, 2.7182818284 590452348, 2.7182818284 590452354,
    ...]
                      Type: Stream Float

Compare this to the value of e computed by the exp operation in Float.

  exp 1.0
   2.7182818284 590452354
                      Type: Float

In about 1658, Lord Brouncker established the following expansion
for 4 / pi,

         1 +           1
             -----------------------
             2 +           9
```

```
                  ------------------
                  2 +        25
                      ---------------
                      2 +      49
                          -----------
                          2 +    81
                              -------
                              2 + ...
```

Let's use this expansion to compute rational and floating point approximations for pi.

```
  cf := continuedFraction(1,[(2*i+1)**2 for i in 0..],repeating [2])
           1 |     9 |     25 |     49 |     81 |     121 |     169 |     225 |
     1 + +---+ + +---+ + +----+ + +----+ + +----+ + +-----+ + +-----+ + +-----+
         | 2     | 2     | 2      | 2      | 2      |  2      |  2      |  2
   +
       289 |     361 |
     +-----+ + +-----+ + ...
     |  2      |  2
                       Type: ContinuedFraction Integer

  ccf := convergents cf
      3 15 105 315 3465 45045 45045 765765 14549535
   [1,-,--,---,---,----,-----,-----,------,--------,...]
      2 13  76 263 2578 36979 33976 622637 11064338
                       Type: Stream Fraction Integer

  piConvergents := [4/p for p in ccf]
      8 52 304 1052 10312 147916 135904 2490548 44257352
   [4,-,--,---,----,-----,------,------,-------,--------,...]
      3 15 105  315  3465  45045  45045  765765 14549535
                       Type: Stream Fraction Integer
```

As you can see, the values are converging to pi = 3.14159265358979323846..., but not very quickly.

```
  piConvergents :: Stream Float
   [4.0, 2.6666666666 666666667, 3.4666666666 666666667,
    2.8952380952 380952381, 3.3396825396 825396825, 2.9760461760 461760462,
    3.2837384837 384837385, 3.0170718170 718170718, 3.2523659347 188758953,
    3.0418396189 294022111, ...]
                      Type: Stream Float
```

You need not restrict yourself to continued fractions of integers. Here is an expansion for a quotient of Gaussian integers.

```
  continuedFraction((- 122 + 597*%i)/(4 - 4*%i))
                       1    |         1     |
   - 90 + 59%i + +---------+ + +-----------+
```

```
                | 1 - 2%i     | - 1 + 2%i
                     Type: ContinuedFraction Complex Integer
```

This is an expansion for a quotient of polynomials in one variable
with rational number coefficients.

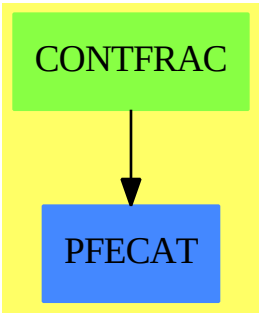
```
  r : Fraction UnivariatePolynomial(x,Fraction Integer)
                     Type: Void

  r := ((x - 1) * (x - 2)) / ((x-3) * (x-4))
     2
    x  - 3x + 2
   ------------
    2
   x  - 7x + 12
                     Type: Fraction UnivariatePolynomial(x,Fraction Integer)

  continuedFraction r
            1    |         1     |
   1 + +---------+ + +-----------+
       | 1     9     | 16     40
       | - x - -     | -- x - --
       | 4     8     |  3      3
             Type: ContinuedFraction UnivariatePolynomial(x,Fraction Integer)
```

To conclude this section, we give you evidence that

```
    z = 3 +            1
            -----------------------
            3 +          1
                -------------------
                6 +        1
                    ---------------
                    3 +      1
                        -----------
                        6 +    1
                            -------
                            3 + ...
```



is the expansion of sqrt(11).

```
  [i*i for i in convergents(z) :: Stream Float]
   [9.0, 11.1111111111 11111111, 10.9944598337 9501385, 11.0002777777 77777778,
    10.9999860763 98799786, 11.0000006979 29731039, 10.9999999650 15834446,
    11.0000000017 53603304, 10.9999999999 12099531, 11.0000000000 04406066,
    ...]
                     Type: Stream Float
```

— domain CONTFRAC ContinuedFraction —

```
)abbrev domain CONTFRAC ContinuedFraction
++ Author: Stephen M. Watt
++ Date Created: January 1987
```

```
++ Change History: 7 October 1991
++ Description:
++ \spadtype{ContinuedFraction} implements general
++ continued fractions.  This version is not restricted to simple,
++ finite fractions and uses the \spadtype{Stream} as a
++ representation.  The arithmetic functions assume that the
++ approximants alternate below/above the convergence point.
++ This is enforced by ensuring the partial numerators and partial
++ denominators are greater than 0 in the Euclidean domain view of \spad{R}
++ (i.e. \spad{sizeLess?(0, x)}).

ContinuedFraction(R): Exports == Implementation where
  R :     EuclideanDomain
  Q   ==> Fraction R
  MT  ==> MoebiusTransform Q
  OUT ==> OutputForm

  Exports ==> Join(Algebra R,Algebra Q,Field) with
    continuedFraction:        Q -> %
      ++ continuedFraction(r) converts the fraction \spadvar{r} with
      ++ components of type \spad{R} to a continued fraction over
      ++ \spad{R}.

    continuedFraction:        (R, Stream R, Stream R) -> %
      ++ continuedFraction(b0,a,b) constructs a continued fraction in
      ++ the following way:  if \spad{a = [a1,a2,...]} and \spad{b =
      ++ [b1,b2,...]} then the result is the continued fraction
      ++ \spad{b0 + a1/(b1 + a2/(b2 + ...))}.

    reducedContinuedFraction: (R, Stream R) -> %
      ++ reducedContinuedFraction(b0,b) constructs a continued
      ++ fraction in the following way:  if \spad{b = [b1,b2,...]}
      ++ then the result is the continued fraction \spad{b0 + 1/(b1 +
      ++ 1/(b2 + ...))}.  That is, the result is the same as
      ++ \spad{continuedFraction(b0,[1,1,1,...],[b1,b2,b3,...])}.

    partialNumerators:   % -> Stream R
      ++ partialNumerators(x) extracts the numerators in \spadvar{x}.
      ++ That is, if \spad{x = continuedFraction(b0, [a1,a2,a3,...],
      ++ [b1,b2,b3,...])}, then \spad{partialNumerators(x) =
      ++ [a1,a2,a3,...]}.

    partialDenominators: % -> Stream R
      ++ partialDenominators(x) extracts the denominators in
      ++ \spadvar{x}.  That is, if \spad{x = continuedFraction(b0,
      ++ [a1,a2,a3,...], [b1,b2,b3,...])}, then
      ++ \spad{partialDenominators(x) = [b1,b2,b3,...]}.

    partialQuotients:    % -> Stream R
      ++ partialQuotients(x) extracts the partial quotients in
```

```
      ++ \spadvar{x}.  That is, if \spad{x = continuedFraction(b0,
      ++ [a1,a2,a3,...], [b1,b2,b3,...])}, then
      ++ \spad{partialQuotients(x) = [b0,b1,b2,b3,...]}.

    wholePart:           % -> R
      ++ wholePart(x) extracts the whole part of \spadvar{x}.  That
      ++ is, if \spad{x = continuedFraction(b0, [a1,a2,a3,...],
      ++ [b1,b2,b3,...])}, then \spad{wholePart(x) = b0}.

    reducedForm:         % -> %
      ++ reducedForm(x) puts the continued fraction \spadvar{x} in
      ++ reduced form, i.e.  the function returns an equivalent
      ++ continued fraction of the form
      ++ \spad{continuedFraction(b0,[1,1,1,...],[b1,b2,b3,...])}.

    approximants:        % -> Stream Q
      ++ approximants(x) returns the stream of approximants of the
      ++ continued fraction \spadvar{x}. If the continued fraction is
      ++ finite, then the stream will be infinite and periodic with
      ++ period 1.

    convergents:         % -> Stream Q
      ++ convergents(x) returns the stream of the convergents of the
      ++ continued fraction \spadvar{x}. If the continued fraction is
      ++ finite, then the stream will be finite.

    numerators:          % -> Stream R
      ++ numerators(x) returns the stream of numerators of the
      ++ approximants of the continued fraction \spadvar{x}. If the
      ++ continued fraction is finite, then the stream will be finite.

    denominators:        % -> Stream R
      ++ denominators(x) returns the stream of denominators of the
      ++ approximants of the continued fraction \spadvar{x}. If the
      ++ continued fraction is finite, then the stream will be finite.

    extend:              (%,Integer) -> %
      ++ extend(x,n) causes the first \spadvar{n} entries in the
      ++ continued fraction \spadvar{x} to be computed.  Normally
      ++ entries are only computed as needed.

    complete:            % -> %
      ++ complete(x) causes all entries in \spadvar{x} to be computed.
      ++ Normally entries are only computed as needed.  If \spadvar{x}
      ++ is an infinite continued fraction, a user-initiated interrupt is
      ++ necessary to stop the computation.

DecimalExpansion examples
========================================================================

All rationals have repeating decimal expansions.  Operations to access
the individual digits of a decimal expansion can be obtained by
converting the value to RadixExpansion(10).

The operation decimal is used to create this expansion of type
DecimalExpansion.

  r := decimal(22/7)
       ------
    3.142857
                      Type: DecimalExpansion

Arithmetic is exact.

  r + decimal(6/7)
   4
                      Type: DecimalExpansion

The period of the expansion can be short or long ...

  [decimal(1/i) for i in 350..354]

Denavit-Hartenberg Matrices

Homogeneous Transformations

The study of robot manipulation is concerned with the relationship between objects, and between objects and manipulators. In this chapter we will develop the representation necessary to describe these relationships. Similar problems of representation have already been solved in the field of computer graphics, where the relationship between objects must also be

described. Homogeneous transformations are used in this field and in computer vision [Duda] [Robserts63] [Roberts65]. These transformations were employed by Denavit to describe linkages [Denavit] and are now used to describe manipulators [Pieper] [Paul72] [Paul77b].

We will first establish notation for vectors and planes and then introduce transformations on them. These transformations consist primarily of translation and rotation. We will then show that these transformations can also be considered as coordinate frames in which to represent objects, including the manipulator. The inverse transformation will then be introduced. A later section describes the general rotation transformation representing a rotation about a vector. An algorithm is then described to find the equivalent axis and angle of rotations represented by any given transformation. A brief section on stretching and scaling transforms is included together with a section on the perspective transformation. The chapter concludes with a section on transformation equations.

Notation

In describing the relationship between objects we will make use of point vectors, planes, and coordinate frames. Point vectors are denoted by lower case, bold face characters. Planes are denoted by script characters, and coordinate frames by upper case, bold face characters. For example:

vectors	**v**, **x1**, **x**
planes	$\mathcal{P}$, $\mathcal{Q}$
coordinate frames	**I**, **A**, **CONV**

We will use point vectors, planes, and coordinate frames as variables which have associated values. For example, a point vector has as value its three Cartesian coordinate components.

If we wish to describe a point in space, which we will call p, with respect to a coordinate frame **E**, we will use a vector which we will call **v**. We will write this as

$$^{E}\mathbf{v}$$

The leading superscript describes the defining coordinate frame.

We might also wish to describe this same point, p, with respect to a different coordinate frame, for example **H**, using a vector **w** as

$$^{H}\mathbf{w}$$

v and **w** are two vectors which probably have different component values and $\mathbf{v} \neq \mathbf{w}$ even though both vectors describe the same point p. The case might also exist of a vector **a** describing a point 3 inches above any frame

$$^{F^1}\mathbf{a} \qquad ^{F^2}\mathbf{a}$$

In this case the vectors are identical but describe different points. Frequently, the defining frame will be obvious from the text and the superscripts will be left off. In many cases the

name of the vector will be the same as the name of the object described, for example, the tip of a pin might be described by a vector **tip** with respect to a frame **BASE** as

$$^{BASE}\mathbf{tip}$$

If it were obvious from the text that we were describing the vector with respect to **BASE** then we might simply write

$$\mathbf{tip}$$

If we also wish to describe this point with respect to another coordinate frame say, **HAND**, then we must use another vector to describe this relationship, for example

$$^{HAND}\mathbf{tv}$$

$^{HAND}\mathbf{tv}$ and **tip** both describe the same feature but have different values. In order to refer to individual components of coordinate frames, point vectors, or planes, we add subscripts to indicate the particular component. For example, the vector $^{HAND}\mathbf{tv}$ has components $^{HAND}\mathbf{tv_x}$, $^{HAND}\mathbf{tv_y}$, $^{HAND}\mathbf{tv_z}$.

Vectors

The homogeneous coordinate representation of objects in n-space is an $(n+1)$-space entity such that a particular perspective projection recreates the n-space. This can also be viewed as the addition of an extra coordinate to each vector, a scale factor, such that the vector has the same meaning if each component, including the scale factor, is multiplied by a constant.

A point vector

$$\mathbf{v} = a\mathbf{i} + b\mathbf{j} + c\mathbf{k} \tag{1.1}$$

where **i**, **j**, and **k** are unit vectors along the x, y, and z coordinate axes, respectively, is represented in homogeneous coordinates as a column matrix

$$\mathbf{v} = \begin{bmatrix} \mathbf{x} \\ \mathbf{y} \\ \mathbf{z} \\ \mathbf{w} \end{bmatrix} \tag{1.2}$$

where

$$\begin{aligned} \mathbf{a} &= \mathbf{x}/\mathbf{w} \\ \mathbf{b} &= \mathbf{y}/\mathbf{w} \\ \mathbf{c} &= \mathbf{z}/\mathbf{w} \end{aligned} \tag{1.3}$$

Thus the vector $3\mathbf{i} + 4\mathbf{j} + 5\mathbf{k}$ can be represented as $[3, 4, 5, 1]^{\mathrm{T}}$ or as $[6, 8, 10, 2]^{\mathrm{T}}$ or again as $[-30, -40, -50, -10]^{\mathrm{T}}$, etc. The superscript T indicates the transpose of the row vector into a column vector. The vector at the origin, the null vector, is represented as $[0, 0, 0, n]^{\mathrm{T}}$ where n is any non-zero scale factor. The vector $[0, 0, 0, 0]^{\mathrm{T}}$ is undefined. Vectors of the form $[a, b, c, 0]^{\mathrm{T}}$ represent vectors at infinity and are used to represent directions; the addition of any other finite vector does not change their value in any way.

We will also make use of the vector dot and cross products. Given two vectors

$$\begin{aligned} \mathbf{a} &= a_x\mathbf{i} + a_y\mathbf{j} + a_z\mathbf{k} \\ \mathbf{b} &= b_x\mathbf{i} + b_y\mathbf{j} + b_z\mathbf{k} \end{aligned} \tag{1.4}$$

we define the vector dot product, indicated by "$\cdot$" as

$$\mathbf{a} \cdot \mathbf{b} = a_x b_x + a_y b_y + a_z b_z \tag{1.5}$$

The dot product of two vectors is a scalar. The cross product, indicated by an "$\times$", is another vector perpendicular to the plane formed by the vectors of the product and is defined by

$$\mathbf{a} \times \mathbf{b} = (a_y b_z - a_z b_y)\mathbf{i} + (a_z b_x - a_x b_z)\mathbf{j} + (a_x b_y - a_y b_x)\mathbf{k} \tag{1.6}$$

This definition is easily remembered as the expansion of the determinant

$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_x & a_y & a_z \\ b_x & b_y & b_z \end{vmatrix} \tag{1.7}$$

Planes

A plane is represented as a row matrix

$$\mathcal{P} = [a, b, c, d] \tag{1.8}$$

such that if a point $\mathbf{v}$ lies in a plane $\mathcal{P}$ the matrix product

$$\mathcal{P}\ \mathbf{v} = 0 \tag{1.9}$$

or in expanded form

$$xa + yb + zc + wd = 0 \tag{1.10}$$

If we define a constant

$$m = +\sqrt{a^2 + b^2 + c^2} \tag{1.11}$$

and divide Equation 1.10 by wm we obtain

$$\frac{x}{w}\frac{a}{m} + \frac{y}{w}\frac{b}{m} + \frac{z}{w}\frac{c}{m} = -\frac{d}{m} \tag{1.12}$$

The left hand side of Equation 1.12 is the vector dot product of two vectors $(x/w)\mathbf{i} + (y/w)\mathbf{j} + (z/w)\mathbf{k}$ and $(a/m)\mathbf{i} + (b/m)\mathbf{j} + (c/m)\mathbf{k}$ and represents the directed distance of the point $(x/w)\mathbf{i} + (y/w)\mathbf{j} + (z/w)\mathbf{k}$ along the vector
$(a/m)\mathbf{i} + (b/m)\mathbf{j} + (c/m)\mathbf{k}$. The vector $(a/m)\mathbf{i} + (b/m)\mathbf{j} + (c/m)\mathbf{k}$ can be interpreted as the outward pointing normal of a plane situated a distance $-d/m$ from the origin in the direction of the normal. Thus a plane $\mathcal{P}$ parallel to the x,y plane, one unit along the z axis, is represented as

$$\mathcal{P} = [0, 0, 1, -1] \tag{1.13}$$

$$\text{or as} \quad \mathcal{P} = [0, 0, 2, -2] \tag{1.14}$$

$$\text{or as} \quad \mathcal{P} = [0, 0, -100, 100] \tag{1.15}$$

A point $\mathbf{v} = [10, 20, 1, 1]$ should lie in this plane

$$[0, 0, -100, 100] \begin{bmatrix} 10 \\ 20 \\ 1 \\ 1 \end{bmatrix} = 0 \tag{1.16}$$

or

$$[0, 0, 1, -1] \begin{bmatrix} -5 \\ -10 \\ -.5 \\ -.5 \end{bmatrix} = 0 \tag{1.17}$$

The point $\mathbf{v} = [0, 0, 2, 1]$ lies above the plane

$$[0, 0, 2, -2] \begin{bmatrix} 0 \\ 0 \\ 2 \\ 1 \end{bmatrix} = 2 \tag{1.18}$$

and $\mathcal{P}$ $\mathbf{v}$ is indeed positive, indicating that the point is outside the plane in the direction of the outward pointing normal. A point $\mathbf{v} = [0, 0, 0, 1]$ lies below the plane

$$[0, 0, 1, -1] \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} = -1 \tag{1.19}$$

The plane $[0, 0, 0, 0]$ is undefined.

Transformations

A transformation of the space $\mathbf{H}$ is a 4x4 matrix and can represent translation, rotation, stretching, and perspective transformations. Given a point $\mathbf{u}$, its transformation $\mathbf{v}$ is represented by the matrix product

$$\mathbf{v} = \mathbf{H}\mathbf{u} \tag{1.20}$$

The corresponding plane transformation $\mathcal{P}$ to $\mathcal{Q}$ is

$$\mathcal{Q}{=}\mathcal{P}\ \mathbf{H^{-1}} \tag{1.21}$$

as we requre that the condition

$$\mathcal{Q}\ \mathbf{v} = \mathcal{P}\ \mathbf{u} \tag{1.22}$$

is invariant under all transformations. To verify this we substitute from Equations 1.20 and 1.21 into the left hand side of 1.22 and we obtain on the right hand side $\mathbf{H^{-1}H}$ which is the identity matrix $\mathbf{I}$

$$\mathcal{P}\ \mathbf{H^{-1}Hu} = \mathcal{P}\ \mathbf{u} \tag{1.23}$$

Translation Transformation

The transformation $\mathbf{H}$ corresponding to a translation by a vector $a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$ is

$$\mathbf{H} = \mathbf{Trans}(\mathbf{a}, \mathbf{b}, \mathbf{c}) = \begin{bmatrix} 1 & 0 & 0 & a \\ 0 & 1 & 0 & b \\ 0 & 0 & 1 & c \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.24}$$

Given a vector $\mathbf{u} = [x, y, z, w]^{\mathrm{T}}$ the transformed vector $\mathbf{v}$ is given by

$$\mathbf{H} = \mathbf{Trans}(\mathbf{a}, \mathbf{b}, \mathbf{c}) = \begin{bmatrix} 1 & 0 & 0 & a \\ 0 & 1 & 0 & b \\ 0 & 0 & 1 & c \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ w \end{bmatrix} \tag{1.25}$$

$$\mathbf{v} = \begin{bmatrix} x + aw \\ y + bw \\ z + cw \\ w \end{bmatrix} = \begin{bmatrix} x/w + a \\ y/w + b \\ z/w + c \\ 1 \end{bmatrix} \tag{1.26}$$

The translation may also be interpreted as the addition of the two vectors $(x/w)\mathbf{i} + (y/w)\mathbf{j} + (z/w)\mathbf{k}$ and $a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$.

Every element of a transformation matrix may be multiplied by a non-zero constant without changing the transformation, in the same manner as points and planes. Consider the vector $2\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ translated by, or added to
$4\mathbf{i}$ - $3\mathbf{j}$ + $7\mathbf{k}$

$$\begin{bmatrix} 6 \\ 0 \\ 9 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 4 \\ 0 & 1 & 0 & -3 \\ 0 & 0 & 1 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 2 \\ 3 \\ 2 \\ 1 \end{bmatrix} \tag{1.27}$$

If we multiply the transmation matrix elements by, say, -5, and the vector elements by 2, we obtain

$$\begin{bmatrix} -60 \\ 0 \\ -90 \\ -10 \end{bmatrix} = \begin{bmatrix} -5 & 0 & 0 & -20 \\ 0 & -5 & 0 & 15 \\ 0 & 0 & -5 & -35 \\ 0 & 0 & 0 & -5 \end{bmatrix} \begin{bmatrix} 4 \\ 6 \\ 4 \\ 2 \end{bmatrix} \tag{1.28}$$

which corresponds to the vector $[6, 0, 9, 1]^{\mathrm{T}}$ as before. The point $[2, 3, 2, 1]$ lies in the plane $[1, 0, 0, -2]$

$$[1, 0, 0, -2] \begin{bmatrix} 2 \\ 3 \\ 2 \\ 1 \end{bmatrix} = 0 \tag{1.29}$$

The transformed point is, as we have already found, $[6, 0, 9, 1]^{\mathrm{T}}$. We will now compute the transformed plane. The inverse of the transform is

$$\begin{bmatrix} 1 & 0 & 0 & -4 \\ 0 & 1 & 0 & 3 \\ 0 & 0 & 1 & -7 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

and the transformed plane

$$[1\ 0\ 0\ -6] = [1\ 0\ 0\ -2] \begin{bmatrix} 1 & 0 & 0 & -4 \\ 0 & 1 & 0 & 3 \\ 0 & 0 & 1 & -7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.30}$$

Once again the transformed point lies in the transformed plane

$$[1\ 0\ 0\ -6] \begin{bmatrix} 6 \\ 0 \\ 9 \\ 1 \end{bmatrix} = 0 \tag{1.31}$$

The general translation operation can be represented in Axiom as

— **translate** —

```
translate(x,y,z) ==
 matrix(_
  [[1,0,0,x],_
   [0,1,0,y],_
   [0,0,1,z],_
   [0,0,0,1]])
```

———-

Rotation Transformations

The transformations corresponding to rotations about the x, y, and z axes by an angle θ are

$$\mathbf{Rot}(\mathbf{x},\theta) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & cos\ \theta & -sin\ \theta & 0 \\ 0 & sin\ \theta & cos\ \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.32}$$

Rotations can be described in Axiom as functions that return matrices. We can define a function for each of the rotation matrices that correspond to the rotations about each axis. Note that the sine and cosine functions in Axiom expect their argument to be in radians rather than degrees. This conversion is

$$radians = \frac{degrees * \pi}{180}$$

The Axiom code for $\mathbf{Rot}(\mathbf{x},\mathbf{degree})$ is

— **rotatex** —

```
rotatex(degree) ==
 angle := degree * pi() / 180::R
 cosAngle := cos(angle)
 sinAngle := sin(angle)
 matrix(_
  [[1,     0,           0,      0], _
   [0, cosAngle, -sinAngle, 0], _
   [0, sinAngle,  cosAngle, 0], _
   [0,     0,           0,      1]])
```

———-

$$\mathbf{Rot}(\mathbf{y},\theta) = \begin{bmatrix} cos\ \theta & 0 & sin\ \theta & 0 \\ 0 & 1 & 0 & 0 \\ -sin\ \theta & 0 & cos\ \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.33}$$

The Axiom code for $\mathbf{Rot}(\mathbf{y},\mathbf{degree})$ is

— **rotatey** —

```
rotatey(degree) ==
 angle := degree * pi() / 180::R
 cosAngle := cos(angle)
 sinAngle := sin(angle)
 matrix(_
  [[ cosAngle, 0, sinAngle, 0], _
   [    0,       1,     0,      0], _
   [-sinAngle, 0, cosAngle, 0], _
   [    0,       0,     0,      1]])
```

———-

$$\mathbf{Rot}(\mathbf{z},\theta) = \begin{bmatrix} cos\ \theta & -sin\ \theta & 0 & 0 \\ sin\ \theta & cos\ \theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.34}$$

And the Axiom code for $\mathbf{Rot}(\mathbf{z},\mathbf{degree})$ is

— **rotatez** —

```
rotatez(degree) ==
 angle := degree * pi() / 180::R
 cosAngle := cos(angle)
 sinAngle := sin(angle)
 matrix(_
  [[cosAngle, -sinAngle, 0, 0], _
   [sinAngle,  cosAngle, 0, 0], _
   [   0,           0,       1, 0], _
   [   0,           0,       0, 1]])
```

———-

Let us interpret these rotations by means of an example. Given a point $\mathbf{u} = 7\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ what is the effect of rotating it 90° about the $\mathbf{z}$ axis to $\mathbf{v}$? The transform is obtained from Equation 1.34 with $sin\ \theta = 1$ and $cos\ \theta = 0$.

$$\begin{bmatrix} -3 \\ 7 \\ 2 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \tag{1.35}$$

Let us now rotate $\mathbf{v}$ 90° about the y axis to $\mathbf{w}$. The transform is obtained from Equation 1.33 and we have

$$\begin{bmatrix} 2 \\ 7 \\ 3 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} -3 \\ 7 \\ 2 \\ 1 \end{bmatrix} \tag{1.36}$$

If we combine these two rotations we have

$$\mathbf{v} = \mathbf{Rot}(\mathbf{z}, \mathbf{90})\mathbf{u} \tag{1.37}$$

$$\text{and} \quad \mathbf{w} = \mathbf{Rot}(\mathbf{y}, \mathbf{90})\mathbf{v} \tag{1.38}$$

Substituting for $\mathbf{v}$ from Equation 1.37 into Equation 1.38 we obtain

$$\mathbf{w} = \mathbf{Rot}(\mathbf{y}, \mathbf{90})\ \mathbf{Rot}(\mathbf{z}, \mathbf{90})\ \mathbf{u} \tag{1.39}$$

$$\mathbf{Rot}(\mathbf{y}, \mathbf{90})\ \mathbf{Rot}(\mathbf{z}, \mathbf{90}) = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.40}$$

$$\mathbf{Rot}(\mathbf{y}, \mathbf{90})\ \mathbf{Rot}(\mathbf{z}, \mathbf{90}) = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.41}$$

thus

$$\mathbf{w} = \begin{bmatrix} 2 \\ 7 \\ 3 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \tag{1.42}$$

as we obtained before.

If we reverse the order of rotations and first rotate 90° about the y axis and then 90° about the z axis, we obtain a different position

$$\mathbf{Rot}(\mathbf{z},\mathbf{90})\mathbf{Rot}(\mathbf{y},\mathbf{90}) = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.43}$$

and the point $\mathbf{u}$ transforms into $\mathbf{w}$ as

$$\begin{bmatrix} -3 \\ 2 \\ -7 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \tag{1.44}$$

We should expect this, as matrix multiplication is noncommutative.

$$\mathbf{AB} \neq \mathbf{BA} \tag{1.45}$$

We will now combine the original rotation with a translation $4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$. We obtain the translation from Equation 1.27 and the rotation from Equation 1.41. The matrix expression is

$$\mathbf{Trans}(\mathbf{4},\mathbf{-3},\mathbf{7})\mathbf{Rot}(\mathbf{y},\mathbf{90})\mathbf{Rot}(\mathbf{z},\mathbf{90}) = \begin{bmatrix} 1 & 0 & 0 & 4 \\ 0 & 1 & 0 & -3 \\ 0 & 0 & 1 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.46}$$

and our point $\mathbf{w} = 7\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ transforms into $\mathbf{x}$ as

$$\begin{bmatrix} 6 \\ 4 \\ 10 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \tag{1.47}$$

Coordinate Frames

We can interpret the elements of the homogeneous transformation as four vectors describing a second coordinate frame. The vector $[0, 0, 0, 1]^{\mathrm{T}}$ lies at the origin of the second coordinate frame. Its transformation corresponds to the right hand column of the transformation matrix. Consider the transform in Equation 1.47

$$\begin{bmatrix} 4 \\ -3 \\ 7 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} \tag{1.48}$$

The transform of the null vector is $[4, -3, 7, 1]^{\mathrm{T}}$, the right hand column. If we transform vectors corresponding to unit vectors along the x, y, and z axes, we obtain $[4, -2, 7, 1]^{\mathrm{T}}$, $[4, -3, 8, 1]^{\mathrm{T}}$, and $[5, -3, 7, 1]^{\mathrm{T}}$, respectively. Those four vectors form a coordinate frame.

The direction of these unit vectors is formed by subtracting the vector representing the origin of this coordinate frame and extending the vectors to infinity by reducing their scale factors to zero. The direction of the x, y, and z axes of this frame are $[0, 1, 0, 0]^{\mathrm{T}}$, $[0, 0, 1, 0]^{\mathrm{T}}$, and $[1, 0, 0, 0]^{\mathrm{T}}$, respectively. These direction vectors correspond to the first three columns of the transformation matrix. The transformation matrix thus describes the three axis directions and the position of the origin of a coordinate frame rotated and translated away from the reference coordinate frame. When a vector is transformed, as in Equation 1.47, the original vector can be considered as a vector described in the coordinate frame. The transformed vector is the same vector described with respect to the reference coordinate frame.

Relative Transformations

The rotations and translations we have been describing have all been made with respect to the fixed reference coordinate frame. Thus, in the example given,

$$\mathbf{Trans}(\mathbf{4}, \mathbf{-3}, \mathbf{7})\mathbf{Rot}(\mathbf{y}, \mathbf{90})\mathbf{Rot}(\mathbf{z}, \mathbf{90}) = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.49}$$

the frame is first rotated around the reference z axis by 90°, then rotated 90° around the reference y axis, and finally translated by $4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$. We may also interpret the operation in the reverse order, from left to right, as follows: the object is first translated by $4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$; it is then rotated 90° around the current frames axes, which in this case are the same as the reference axes; it is then rotated 90° about the newly rotated (current) frames axes.

In general, if we postmultiply a transform representing a frame by a second transformation describing a rotation and/or translation, we make that translation and/or rotation with respect to the frame axes described by the first transformation. If we premultiply the frame transformation by a transformation representing a translation and/or rotation, then that translation and/or rotation is made with respect to the base reference coordinate frame. Thus, given a frame $\mathbf{C}$ and a transformation $\mathbf{T}$, corresponding to a rotation of 90° about the z axis, and a translation of 10 units in the x direction, we obtain a new position $\mathbf{X}$ when the change is made in the base coordinates $\mathbf{X} = \mathbf{TC}$

$$\begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 20 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 10 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 20 \\ 0 & 0 & -1 & 10 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.50}$$

and a new position $\mathbf{Y}$ when the change is made relative to the frame axes as $\mathbf{Y} = \mathbf{CT}$

$$\begin{bmatrix} 0 & -1 & 0 & 30 \\ 0 & 0 & -1 & 10 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 20 \\ 0 & 0 & -1 & 10 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -1 & 0 & 10 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.51}$$

Objects

Transformations are used to describe the position and orientation of objects. An object is described by six points with respect to a coordinate frame fixed in the object.

If we rotate the object 90° about the z axis and then 90° about the y axis, followed by a translation of four units in the x direction, we can describe the transformation as

$$\mathbf{Trans}(\mathbf{4},\mathbf{0},\mathbf{0})\mathbf{Rot}(\mathbf{y},\mathbf{90})\mathbf{Rot}(\mathbf{z},\mathbf{90}) = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.52}$$

The transformation matrix represents the operation of rotation and translation on a coordinate frame originally aligned with the reference coordinate frame. We may transform the six points of the object as

$$\begin{bmatrix} 4 & 4 & 6 & 6 & 4 & 4 \\ 1 & -1 & -1 & 1 & 1 & -1 \\ 0 & 0 & 0 & 0 & 4 & 4 \\ 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 & -1 & 1 & 1 & -1 \\ 0 & 0 & 0 & 0 & 4 & 4 \\ 0 & 0 & 2 & 2 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \tag{1.53}$$

It can be seen that the object described bears the same fixed relationship to its coordinate frame, whose position and orientation are described by the transformation. Given an object described by a reference coordinate frame, and a transformation representing the position and orientation of the object's axes, the object can be simply reconstructed, without the necessity of transforming all the points, by noting the direction and orientation of key features with respect to the describing frame's coordinate axes. By drawing the transformed coordinate frame, the object can be related to the new axis directions.

Inverse Transformations

We are now in a position to develop the inverse transformation as the transform which carries the transformed coordinate frame back to the original frame. This is simply the description of the reference coordinate frame with respect to the transformed frame. Suppose the direction of the reference frame x axis is $[0,0,1,0]^{\mathrm{T}}$ with respect to the transformed frame. The y and z axes are $[1,0,0,0]^{\mathrm{T}}$ and $[0,1,0,0]^{\mathrm{T}}$, respectively. The location of the origin is $[0,0,-4,1]^{\mathrm{T}}$ with respect to the transformed frame and thus the inverse transformation is

$$\mathbf{T^{-1}} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & -4 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.54}$$

That this is indeed the tranform inverse is easily verifyed by multiplying it by the transform $\mathbf{T}$ to obtain the identity transform

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & -4 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.55}$$

In general, given a transform with elements

$$\mathbf{T} = \begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.56}$$

then the inverse is

$$\mathbf{T^{-1}} = \begin{bmatrix} n_x & n_y & n_z & -\mathbf{p} \cdot \mathbf{n} \\ o_x & o_y & o_z & -\mathbf{p} \cdot \mathbf{o} \\ a_x & a_y & a_z & -\mathbf{p} \cdot \mathbf{a} \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.57}$$

where $\mathbf{p}$, $\mathbf{n}$, $\mathbf{o}$, and $\mathbf{a}$ are the four column vectors and "$\cdot$" represents the vector dot product. This result is easily verified by postmultiplying Equation 1.56 by Equation 1.57.

General Rotation Transformation

We state the rotation transformations for rotations about the x, y, and z axes (Equations 1.32, 1.33 and 1.34). These transformations have a simple geometric interpretation. For example, in the case of a rotation about the z axis, the column representing the z axis will remain constant, while the column elements representing the x and y axes will vary.

We will now develop the transformation matrix representing a rotation around an arbitrary vector $\mathbf{k}$ located at the origin. In order to do this we will imagine that $\mathbf{k}$ is the z axis unit vector of a coordinate frame $\mathbf{C}$

$$\mathbf{C} = \begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.58}$$

$$\mathbf{k} = a_x\mathbf{i} + a_y\mathbf{j} + a_z\mathbf{k} \tag{1.59}$$

Rotating around the vector $\mathbf{k}$ is then equivalent to rotating around the z axis of the frame $\mathbf{C}$.

$$\mathbf{Rot}(\mathbf{k}, \theta) = \mathbf{Rot}({}^{\mathbf{C}}\mathbf{z}, \theta) \tag{1.60}$$

If we are given a frame $\mathbf{T}$ described with respect to the reference coordinate frame, we can find a frame $\mathbf{X}$ which describes the same frame with respect to frame $\mathbf{C}$ as

$$\mathbf{T} = \mathbf{CX} \tag{1.61}$$

where $\mathbf{X}$ describes the position of $\mathbf{T}$ with respect to frame $\mathbf{C}$. Solving for $\mathbf{X}$ we obtain

$$\mathbf{X} = \mathbf{C^{-1}T} \tag{1.62}$$

Rotation $\mathbf{T}$ around $\mathbf{k}$ is equivalent to rotating $\mathbf{X}$ around the z axis of frame $\mathbf{C}$

$$\mathbf{Rot}(\mathbf{k}, \theta)\mathbf{T} = \mathbf{CRot}(\mathbf{z}, \theta)\mathbf{X} \tag{1.63}$$

$$\mathbf{Rot}(\mathbf{k}, \theta)\mathbf{T} = \mathbf{CRot}(\mathbf{z}, \theta)\mathbf{C^{-1}T}. \tag{1.64}$$

Thus

$$\mathbf{Rot}(\mathbf{k}, \theta) = \mathbf{CRot}(\mathbf{z}, \theta)\mathbf{C^{-1}} \tag{1.65}$$

However, we have only $\mathbf{k}$, the z axis of the frame $\mathbf{C}$. By expanding equation 1.65 we will discover that $\mathbf{CRot}(\mathbf{z}, \theta)\mathbf{C^{-1}}$ is a function of $\mathbf{k}$ only.

Multiplying $\mathbf{Rot}(\mathbf{z}, \theta)$ on the right by $\mathbf{C^{-1}}$ we obtain

$$\mathbf{Rot}(\mathbf{z}, \theta)\mathbf{C^{-1}} = \begin{bmatrix} cos\theta & -sin\theta & 0 & 0 \\ sin\theta & cos\theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} n_x & n_y & n_z & 0 \\ o_x & o_x & o_z & 0 \\ a_x & a_y & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} n_x cos\theta - o_x sin\theta & n_y cos\theta - o_y sin\theta & n_z cos\theta - o_z sin\theta & 0 \\ n_x sin\theta + o_x cos\theta & n_y sin\theta + o_y cos\theta & n_z sin\theta + o_z cos\theta & 0 \\ a_x & a_y & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.66}$$

premultiplying by

$$\mathbf{C} = \begin{bmatrix} n_x & o_x & a_x & 0 \\ n_y & o_y & a_y & 0 \\ n_z & o_z & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.67}$$

we obtain $\mathbf{CRot}(\mathbf{z},\theta)\mathbf{C^{-1}}$

$$\begin{bmatrix} n_x n_x cos\theta - n_x o_x sin\theta + n_x o_x sin\theta + o_x o_x cos\theta + a_x a_x \\ n_y n_x cos\theta - n_y o_x sin\theta + n_x o_y sin\theta + o_x o_y cos\theta + a_y a_x \\ n_z n_x cos\theta - n_z o_x sin\theta + n_x o_z sin\theta + o_x o_z cos\theta + a_z a_x \\ 0 \end{bmatrix}$$

$$\begin{matrix} n_x n_y cos\theta - n_x o_y sin\theta + n_y o_x sin\theta + o_y o_x cos\theta + a_x a_y \\ n_y n_y cos\theta - n_y o_y sin\theta + n_y o_y sin\theta + o_y o_y cos\theta + a_y a_y \\ n_z n_y cos\theta - n_z o_y sin\theta + n_y o_z sin\theta + o_y o_z cos\theta + a_z a_y \\ 0 \end{matrix} \tag{1.68}$$

$$\begin{bmatrix} n_x n_z cos\theta - n_x o_z sin\theta + n_z o_x sin\theta + o_z o_x cos\theta + a_x a_x & 0 \\ n_y n_z cos\theta - n_y o_z sin\theta + n_z o_y sin\theta + o_z o_y cos\theta + a_y a_z & 0 \\ n_z n_z cos\theta - n_z o_z sin\theta + n_z o_z sin\theta + o_z o_z cos\theta + a_z a_z & 0 \\ 0 & 1 \end{bmatrix}$$

Simplifying, using the following relationships:
the dot product of any row or column of $\mathbf{C}$ with any other row or column is zero, as the vectors are orthogonal;
the dot product of any row or column of $\mathbf{C}$ with itself is $\mathbf{1}$ as the vectors are of unit magnitude;
the z unit vector is the vector cross product of the x and y vectors or

$$\mathbf{a} = \mathbf{n} \times \mathbf{o} \tag{1.69}$$

which has components

$$a_x = n_y o_z - n_z o_y$$
$$a_y = n_z o_x - n_x o_z$$
$$a_z = n_x o_y - n_y o_x$$

the versine, abbreviated **vers** θ, is defined as **vers** $\theta = (1 - cos\ \theta)$, $k_x = a_x$, $k_y = a_y$ and $k_z = a_z$. We obtain $\mathbf{Rot}(\mathbf{k},\theta) =$

$$\begin{bmatrix} k_x k_x vers\theta + cos\theta & k_y k_x vers\theta - k_z sin\theta & k_z k_x vers\theta + k_y sin\theta & 0 \\ k_x k_y vers\theta + k_z sin\theta & k_y k_y vers\theta + cos\theta & k_z k_y vers\theta - k_x sin\theta & 0 \\ k_x k_z vers\theta - k_y sin\theta & k_y k_z vers\theta + k_x sin\theta & k_z k_z vers\theta + cos\theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.70}$$

This is an important result and should be thoroughly understood before proceeding further.

From this general rotation transformation we can obtain each of the elementary rotation transforms. For example $\mathbf{Rot}(\mathbf{x},\theta)$ is $\mathbf{Rot}(\mathbf{k},\theta)$ where $k_x = 1$, $k_y = 0$, and $k_z = 0$. Substituting these values of $\mathbf{k}$ into Equation 1.70 we obtain

$$\mathbf{Rot}(\mathbf{x},\theta) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & cos\theta & -sin\theta & 0 \\ 0 & sin\theta & cos\theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.71}$$

as before.

Equivalent Angle and Axis of Rotation

Given any arbitrary rotational transformation, we can use Equation 1.70 to obtain an axis about which an equivalent rotation θ is made as follows. Given a rotational transformation $\mathbf{R}$

$$\mathbf{R} = \begin{bmatrix} n_x & o_x & a_x & 0 \\ n_y & o_y & a_y & 0 \\ n_z & o_z & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.72}$$

we may equate $\mathbf{R}$ to $\mathbf{Rot(k,\theta)}$

$$\begin{bmatrix} n_x & o_x & a_x & 0 \\ n_y & o_y & a_y & 0 \\ n_z & o_z & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} =$$

$$\begin{bmatrix} k_xk_xvers\theta + cos\theta & k_yk_xvers\theta - k_zsin\theta & k_zk_xvers\theta + k_ysin\theta & 0 \\ k_xk_yvers\theta + k_zsin\theta & k_yk_yvers\theta + cos\theta & k_zk_yvers\theta - k_xsin\theta & 0 \\ k_xk_zvers\theta - k_ysin\theta & k_yk_zvers\theta + k_xsin\theta & k_zk_zvers\theta + cos\theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.73}$$

Summing the diagonal terms of Equation 1.73 we obtain

$$n_x + o_y + a_z + 1 = k_x^2vers\theta + cos\theta + k_y^2vers\theta + cos\theta + k_z^2vers\theta + cos\theta + 1 \tag{1.74}$$

$$\begin{aligned} n_x + o_y + a_z &= (k_x^2 + k_y^2 + k_z^2)vers\theta + 3cos\theta \\ &= 1 + 2cos\theta \end{aligned} \tag{1.75}$$

and the cosine of the angle of rotation is

$$cos\theta = \frac{1}{2}(n_x + o_y + a_z - 1) \tag{1.76}$$

Differencing pairs of off-diagonal terms in Equation 1.73 we obtain

$$o_z - a_y = 2k_x sin\theta \tag{1.77}$$

$$a_x - n_z = 2k_y sin\theta \tag{1.78}$$

$$n_y - o_x = 2k_z sin\theta \tag{1.79}$$

Squaring and adding Equations 1.77-1.79 we obtain an expression for $sin\theta$

$$(o_z - a_y)^2 + (a_x - n_z)^2 + (n_y - o_x)^2 = 4sin^2\theta \tag{1.80}$$

and the sine of the angle of rotation is

$$sin\ \theta = \pm\frac{1}{2}\sqrt{(o_z - a_y)^2 + (a_x - n_z)^2 + (n_y - o_x)^2} \tag{1.81}$$

We may define the rotation to be positive about the vector $\mathbf{k}$ such that $0 \leq \theta \leq 180°$. In this case the + sign is appropriate in Equation 1.81 and thus the angle of rotation θ is uniquely defined as

$$tan\ \theta = \frac{\sqrt{(o_z - a_y)^2 + (a_x - n_z)^2 + (n_y - o_x)^2}}{(n_x + o_y + a_z - 1)} \tag{1.82}$$

The components of $\mathbf{k}$ may be obtained from Equations 1.77-1.79 as

$$k_x = \frac{o_z - a_y}{2sin\theta} \tag{1.83}$$

$$k_y = \frac{a_x - n_z}{2sin\theta} \tag{1.84}$$

$$k_z = \frac{n_y - o_x}{2sin\theta} \tag{1.85}$$

When the angle of rotation is very small, the axis of rotation is physically not well defined due to the small magnitude of both numerator and denominator in Equations 1.83-1.85. If the resulting angle is small, the vector $\mathbf{k}$ should be renormalized to ensure that $|\mathbf{k}| = 1$. When the angle of rotation approaches 180° the vector $\mathbf{k}$ is once again poorly defined by Equation 1.83-1.85 as the magnitude of the sine is again decreasing. The axis of rotation is, however, physically well defined in this case. When $\theta < 150°$, the denominator of Equations 1.83-1.85 is less than 1. As the angle increases to 180° the rapidly decreasing magnitude of both numerator and denominator leads to considerable inaccuracies in the determination of $\mathbf{k}$. At $\theta = 180°$, Equations 1.83-1.85 are of the form 0/0, yielding no information at all about a physically well defined vector $\mathbf{k}$. If the angle of rotation is greater than 90°, then we must follow a different approach in determining $\mathbf{k}$. Equating the diagonal elements of Equation 1.73 we obtain

$$k_x^2 vers\theta + cos\theta = n_x \tag{1.86}$$

$$k_y^2 vers\theta + cos\theta = o_y \tag{1.87}$$

$$k_z^2 vers\theta + cos\theta = a_z \tag{1.88}$$

Substituting for $cos\theta$ and $vers\theta$ from Equation 1.76 and solving for the elements of **k** we obtain further

$$k_x = \pm\sqrt{\frac{n_x - cos\theta}{1 - cos\theta}} \tag{1.89}$$

$$k_y = \pm\sqrt{\frac{o_y - cos\theta}{1 - cos\theta}} \tag{1.90}$$

$$k_z = \pm\sqrt{\frac{a_z - cos\theta}{1 - cos\theta}} \tag{1.91}$$

The largest component of **k** defined by Equations 1.89-1.91 corresponds to the most positive component of n_x, o_y, and a_z. For this largest element, the sign of the radical can be obtained from Equations 1.77-1.79. As the sine of the angle of rotation θ must be positive, then the sign of the component of **k** defined by Equations 1.77-1.79 must be the same as the sign of the left hand side of these equations. Thus we may combine Equations 1.89-1.91 with the information contained in Equations 1.77-1.79 as follows

$$k_x = sgn(o_z - a_y)\sqrt{\frac{(n_x - cos\theta)}{1 - cos\theta}} \tag{1.92}$$

$$k_y = sgn(a_x - n_z)\sqrt{\frac{(o_y - cos\theta)}{1 - cos\theta}} \tag{1.93}$$

$$k_z = sgn(n_y - o_x)\sqrt{\frac{(a_z - cos\theta)}{1 - cos\theta}} \tag{1.94}$$

where $sgn(e) = +1$ if $e \geq 0$ and $sgn(e) = -1$ if $e \leq 0$.

Only the largest element of **k** is determined from Equations 1.92-1.94, corresponding to the most positive element of n_x, o_y, and a_z. The remaining elements are more accurately determined by the following equations formed by summing pairs of off-diagonal elements of Equation 1.73

$$n_y + o_x = 2k_x k_y vers\theta \tag{1.95}$$

$$o_z + a_y = 2k_y k_z vers\theta \tag{1.96}$$

$$n_z + a_x = 2k_z k_x vers\theta \tag{1.97}$$

If k_x is largest then

$$k_y = \frac{n_y + o_x}{2k_x vers\theta} \qquad \text{from Equation 1.95} \tag{1.98}$$

$$k_z = \frac{a_x + n_z}{2k_x vers\theta} \qquad \text{from Equation 1.97} \tag{1.99}$$

If k_y is largest then

$$k_x = \frac{n_y + o_x}{2k_y vers\theta} \qquad \text{from Equation 1.95} \tag{1.100}$$

$$k_z = \frac{o_z + a_y}{2k_y vers\theta} \qquad \text{from Equation 1.96} \tag{1.101}$$

If k_z is largest then

$$k_x = \frac{a_x + n_z}{2k_z vers\theta} \qquad \text{from Equation 1.97} \tag{1.102}$$

$$k_y = \frac{o_z + a_y}{2k_z vers\theta} \qquad \text{from Equation 1.96} \tag{1.103}$$

Example 1.1

Determine the equivalent axis and angle of rotation for the matrix given in Equations 1.41

$$\mathbf{Rot(y, 90)Rot(z, 90)} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.104}$$

We first determine **cos** θ from Equation 1.76

$$cos\theta = \frac{1}{2}(0 + 0 + 0 - 1) = -\frac{1}{2} \tag{1.105}$$

and $sin\ \theta$ from Equation 1.81

$$sin\theta = \frac{1}{2}\sqrt{(1-0)^2 + (1-0)^2 + (1-0)^2} = \frac{\sqrt{3}}{2} \tag{1.106}$$

Thus

$$\theta = tan^{-1}\left(\frac{\sqrt{3}}{2} \Big/ \frac{-1}{2}\right) = 120^\circ \tag{1.107}$$

As $\theta > 90$, we determine the largest component of **k** corresponding to the largest element on the diagonal. As all diagonal elements are equal in this example we may pick any one. We will pick k_x given by Equation 1.92

$$k_x = +\sqrt{(0+\frac{1}{2})\Big/(1+\frac{1}{2})} = \frac{1}{\sqrt{3}} \tag{1.108}$$

As we have determined k_x we may now determine k_y and k_z from Equations 1.98 and 1.99, respectively

$$k_y = \frac{1+0}{\sqrt{3}} = \frac{1}{\sqrt{3}} \tag{1.109}$$

$$k_z = \frac{1+0}{\sqrt{3}} = \frac{1}{\sqrt{3}} \tag{1.110}$$

In summary, then

$$\mathbf{Rot}(\mathbf{y}, \mathbf{90})\mathbf{Rot}(\mathbf{z}, \mathbf{90}) = \mathbf{Rot}(\mathbf{k}, \mathbf{120}) \tag{1.111}$$

where

$$\mathbf{k} = \frac{1}{\sqrt{3}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} + \frac{1}{\sqrt{3}}\mathbf{k} \tag{1.112}$$

Any combination of rotations is always equivalent to a single rotation about some axis $\mathbf{k}$ by an angle θ, an important result that we will make use of later.

Stretching and Scaling

A transform $\mathbf{T}$

$$\mathbf{T} = \begin{bmatrix} a & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & c & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.113}$$

will stretch objects uniformly along the x axis by a factor a, along the y axis by a factor b, and along the z axis by a factor c. Consider any point on an object $x\mathbf{i}+y\mathbf{j}+z\mathbf{k}$; its tranform is

$$\begin{bmatrix} ax \\ by \\ cz \\ 1 \end{bmatrix} = \begin{bmatrix} a & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & c & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} \tag{1.114}$$

indicating stretching as stated. Thus a cube could be transformed into a rectangular parallelepiped by such a transform.

The Axiom code to perform this scale change is:

— **scale** —

```
scale(scalex, scaley, scalez) ==
 matrix(_
  [[scalex, 0      ,0     , 0], _
   [0     , scaley ,0     , 0], _
   [0     , 0,      scalez, 0], _
   [0     , 0,      0     , 1]])
```

———-

The transform **S** where

$$\mathbf{S} = \begin{bmatrix} s & 0 & 0 & 0 \\ 0 & s & 0 & 0 \\ 0 & 0 & s & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{1.115}$$

will scale any object by the factor s.

Perspective Transformations

Consider the image formed of an object by a simple lens.

The axis of the lens is along the y axis for convenience. An object point x,y,z is imaged at x',y',z' if the lens has a focal length f (f is considered positive). y' represents the image distance and varies with object distance y. If we plot points on a plane perpendicular to the y axis located at y' (the film plane in a camera), then a perspective image is formed.

We will first obtain values of x', y', and z', then introduce a perspective transformation and show that the same values are obtained.

Based on the fact that a ray passing through the center of the lens is undeviated we may write

$$\frac{z}{y} = \frac{z'}{y'} \tag{1.116}$$

$$\text{and } \frac{x}{y} = \frac{x'}{y'} \tag{1.117}$$

Based on the additional fact that a ray parallel to the lens axis passes through the focal point f, we may write

$$\frac{z}{f} = \frac{z'}{y' + f} \tag{1.118}$$

$$\text{and } \frac{x}{f} = \frac{x'}{y' + f} \tag{1.119}$$

Notice that x', y', and z' are negative and that f is positive. Eliminating y' between Equations 1.116 and 1.118 we obtain

$$\frac{z}{f} = \frac{z'}{(\frac{z'y}{z} + f)} \tag{1.120}$$

and solving for z' we obtain the result

$$z' = \frac{z}{(1 - \frac{y}{f})} \tag{1.121}$$

Working with Equations 1.117 and 1.119 we can similarly obtain

$$x' = \frac{x}{(1 - \frac{y}{f})} \tag{1.122}$$

In order to obtain the image distance y' we rewrite Equations 1.116 and 1.118 as

$$\frac{z}{z'} = \frac{y}{y'} \tag{1.123}$$

and

$$\frac{z}{z'} = \frac{f}{y' + f} \tag{1.124}$$

thus

$$\frac{y}{y'} = \frac{f}{y' + f} \tag{1.125}$$

and solving for y' we obtain the result

$$y' = \frac{y}{(1 - \frac{y}{f})} \tag{1.126}$$

The homogeneous transformation $\mathbf{P}$ which produces the same result is

$$\mathbf{P} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -\frac{1}{f} & 0 & 1 \end{bmatrix} \tag{1.127}$$

as any point $x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ transforms as

$$\begin{bmatrix} x \\ y \\ z \\ 1-\frac{y}{f} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -\frac{1}{f} & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} \tag{1.128}$$

The image point x', y',, z', obtained by dividing through by the weight factor $(1-\frac{y}{f})$, is

$$\frac{x}{(1-\frac{y}{f})}\mathbf{i} + \frac{y}{(1-\frac{y}{f})}\mathbf{j} + \frac{z}{(1-\frac{y}{f})}\mathbf{k} \tag{1.129}$$

This is the same result that we obtained above.

A transform similar to $\mathbf{P}$ but with $-\frac{1}{f}$ at the bottom of the first column produces a perspective transformation along the x axis. If the $-\frac{1}{f}$ term is in the third column then the projection is along the z axis.

Transform Equations

We will frequently be required to deal with transform equations in which a coordinate frame is described in two or more ways. A manipulator is positioned with respect to base coordinates by a transform $\mathbf{Z}$. The end of the manipulator is described by a transform ${}^{Z}\mathbf{T}_6$, and the end effector is described by ${}^{T_6}\mathbf{E}$. An object is positioned with respect to base coordinates by a transform $\mathbf{B}$, and finally the manipulator end effector is positioned with respect to the object by ${}^{B}\mathbf{G}$. We have two descriptions of the position of the end effector, one with respect to the object and one with respect to the manipulator. As both positions are the same, we may equate the two descriptions

$$\mathbf{Z}\,{}^{Z}\mathbf{T}_6\,{}^{T_6}\mathbf{E} = \mathbf{B}\,{}^{B}\mathbf{G} \tag{1.130}$$

If we wish to solve Equation 1.130 for the manipulator transform $\mathbf{T}_6$ we must premultiply Equation 1.130 by $\mathbf{Z}^{-1}$ and postmultiply by $\mathbf{E}^{-1}$ to obtain

$$\mathbf{T}_6 = \mathbf{Z}^{-1}\mathbf{B}\mathbf{G}\mathbf{E}^{-1} \tag{1.131}$$

As a further example, consider that the position of the object $\mathbf{B}$ is unknown, but that the manipulator is moved such that the end effector is positioned over the object correctly. We may then solve for $\mathbf{B}$ from Equation 1.130 by postmultiplying by $\mathbf{G}^{-1}$.

$$\mathbf{B} = \mathbf{Z}\mathbf{T}_6\mathbf{E}\mathbf{G}^{-1} \tag{1.133}$$

Summary

Homogeneous transformations may be readily used to describe the positions and orientations of coordinate frames in space. If a coordinate frame is embedded in an object then the position and orientation of the object are also readily described.

The description of object A in terms of object B by means of a homogeneous transformation may be inverted to obtain the description of object B in terms of object A. This is not a property of a simple vector description of the relative displacement of one object with respect to another.

Transformations may be interpreted as a product of rotation and translation transformations. If they are intrepreted from left to right, then the rotations and translations are in terms of the currently defined coordinate frame. If they are interpreted from right to left, then the rotations and translations are described with respect to the reference coordinate frame.

Homogeneous transformations describe coordinate frames in terms of rectangular components, which are the sines and cosines of angles. This description may be related to rotations in which case the description is in terms of a vector and angle of rotation.

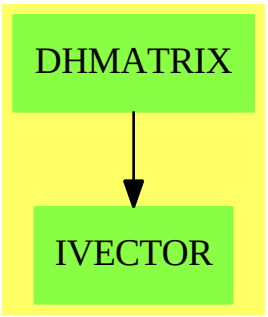
4x4 Matrices for coordinate transformations

This package contains functions to create 4x4 matrices
useful for rotating and transforming coordinate systems.
These matrices are useful for graphics and robotics.
(Reference: Robot Manipulators Richard Paul MIT Press 1981)



A Denavit-Hartenberg Matrix is a 4x4 Matrix of the form:
     nx ox ax px
     ny oy ay py
     nz oz az pz
```

```
    0  0  0  1
where n, o, and a are the direction cosines

See Also:
o )show DenavitHartenbergMatrix

```
=====================================================================
Dequeue examples
=====================================================================

A Dequeue is a double-ended queue so elements can be added to
either end.

Here we create an dequeue of integers from a list. Notice that the
order in the list is the order in the dequeue.

   a:Dequeue INT:= dequeue [1,2,3,4,5]
      [1,2,3,4,5]

We can remove the top of the dequeue using dequeue!:

   dequeue! a
      1

Notice that the use of dequeue! is destructive (destructive operations
in Axiom usually end with ! to indicate that the underylying data
structure is changed).

   a
      [2,3,4,5]

The extract! operation is another name for the dequeue! operation and
has the same effect. This operation treats the dequeue as a BagAggregate:

   extract! a
      2

and you can see that it also has destructively modified the dequeue:

   a
```

```
      [3,4,5]
```

Next we use enqueue! to add a new element to the end of the dequeue:

```
   enqueue!(9,a)
      9
```

Again, the enqueue! operation is destructive so the dequeue is changed:

```
   a
      [3,4,5,9]
```

Another name for enqueue! is insert!, which treats the dequeue as a BagAggregate:

```
   insert!(8,a)
      [3,4,5,9,8]
```

and it modifies the dequeue:

```
   a
      [3,4,5,9,8]
```

The front operation returns the item at the front of the dequeue:

```
   front a
      3
```

The back operation returns the item at the back of the dequeue:

```
   back a
      8
```

The bottom! operation returns the item at the back of the dequeue:

```
   bottom! a
      8
```

and it modifies the dequeue:

```
   a
      [3,4,5,9]
```

The depth function returns the number of elements in the dequeue:

```
   depth a
      4
```

The height function returns the number of elements in the dequeue:

```
   height a
      4

The insertBottom! function adds the element at the end:

   insertBottom!(6,a)
      6

and it modifies the dequeue:

   a
      [3,4,5,9,6]

The extractBottom! function removes the element at the end:

   extractBottom! a
      6

and it modifies the dequeue:

   a
      [3,4,5,9]

The insertTop! function adds the element at the top:

   insertTop!(7,a)
      7

and it modifies the dequeue:

   a
      [7,3,4,5,9]

The extractTop! function adds the element at the top:

   extractTop! a
      7

and it modifies the dequeue:

   a
      [3,4,5,9]

The top function returns the top element:

   top a
      3

and it does not modifies the dequeue:
```

```
   a
      [3,4,5,9]
```

The top! function returns the top element:

```
   top! a
      3
```

and it modifies the dequeue:

```
   a
      [4,5,9]
```

The reverse! operation destructively reverses the elements of the dequeue:

```
   reverse! a
      [9,5,4]
```

The rotate! operation moves the top element to the bottom:

```
   rotate! a
      [5,4,9]
```

The inspect function returns the top of the dequeue without modification, viewed as a BagAggregate:

```
   inspect a
      5
```

The empty? operation returns true only if there are no element on the dequeue, otherwise it returns false:

```
   empty? a
      false
```

The # (length) operation:

```
   #a
       3
```

The length operation does the same thing:

```
   length a
       3
```

The less? predicate will compare the dequeue length to an integer:

```
   less?(a,9)
        true
```

```
The more? predicate will compare the dequeue length to an integer:

   more?(a,9)
        false

The size? operation will compare the dequeue length to an integer:

   size?(a,#a)
        true

and since the last computation must alwasy be true we try:

   size?(a,9)
        false

The parts function will return  the dequeue as a list of its elements:

   parts a
        [5,4,9]

If we have a BagAggregate of elements we can use it to construct a dequeue:

   bag([1,2,3,4,5])$Dequeue(INT)
        [1,2,3,4,5]

The empty function will construct an empty dequeue of a given type:

   b:=empty()$(Dequeue INT)
        []

and the empty? predicate allows us to find out if a dequeue is empty:

   empty? b
        true

The sample function returns a sample, empty dequeue:

   sample()$Dequeue(INT)
        []

We can copy a dequeue and it does not share storage so subsequent
modifications of the original dequeue will not affect the copy:

   c:=copy a
        [5,4,9]

The eq? function is only true if the lists are the same reference,
so even though c is a copy of a, they are not the same:
```

```
   eq?(a,c)
        false
```

However, a clearly shares a reference with itself:

```
   eq?(a,a)
        true
```

But we can compare a and c for equality:

```
   (a=c)@Boolean
        true
```

and clearly a is equal to itself:

```
   (a=a)@Boolean
        true
```

and since a and c are equal, they are clearly NOT not-equal:

```
   a~=c
        false
```

We can use the any? function to see if a predicate is true for any element:

```
   any?(x+->(x=4),a)
        true
```

or false for every element:

```
   any?(x+->(x=11),a)
        false
```

We can use the every? function to check every element satisfies a predicate:

```
   every?(x+->(x=11),a)
        false
```

We can count the elements that are equal to an argument of this type:

```
   count(4,a)
        1
```

or we can count against a boolean function:

```
   count(x+->(x>2),a)
        3
```

You can also map a function over every element, returning a new dequeue:

```
   map(x+->x+10,a)
        [15,14,19]

Notice that the orignal dequeue is unchanged:

   a
        [5,4,9]

You can use map! to map a function over every element and change
the original dequeue since map! is destructive:

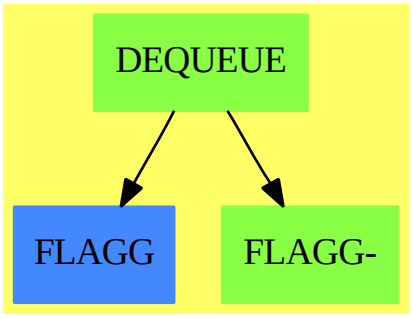
   map!(x+->x+10,a)
       [15,14,19]

Notice that the orignal dequeue has been changed:

   a
       [15,14,19]

The member function can also get the element of the dequeue as a list:

   members a
       [15,14,19]



and using member? we can test if the dequeue holds a given element:

   member?(14,a)
       true

====================================================================
DeRhamComplex examples
====================================================================

The domain constructor DeRhamComplex creates the class of differential
forms of arbitrary degree over a coefficient ring.  The De Rham
complex constructor takes two arguments: a ring, coefRing, and a list
of coordinate variables.

This is the ring of coefficients.
```

```
  coefRing := Integer
   Integer
                      Type: Domain
```

These are the coordinate variables.

```
  lv : List Symbol := [x,y,z]
   [x,y,z]
                      Type: List Symbol
```

This is the De Rham complex of Euclidean three-space using coordinates x, y and z.

```
  der := DERHAM(coefRing,lv)
   DeRhamComplex(Integer,[x,y,z])
                      Type: Domain
```

This complex allows us to describe differential forms having expressions of integers as coefficients. These coefficients can involve any number of variables, for example, f(x,t,r,y,u,z). As we've chosen to work with ordinary Euclidean three-space, expressions involving these forms are treated as functions of x, y and z with the additional arguments t, r and u regarded as symbolic constants.

Here are some examples of coefficients.

```
  R := Expression coefRing
   Expression Integer
                     Type: Domain

  f : R := x**2*y*z-5*x**3*y**2*z**5
       3 2 5    2
   - 5x y z  + x y z
                     Type: Expression Integer

  g : R := z**2*y*cos(z)-7*sin(x**3*y**2)*z**2
       2     3 2       2
   - 7z sin(x y ) + y z cos(z)
                     Type: Expression Integer

  h : R :=x*y*z-2*x**3*y*z**2
       3   2
   - 2x y z  + x y z
                     Type: Expression Integer
```

We now define the multiplicative basis elements for the exterior algebra over R.

```
  dx : der := generator(1)
```

```
   dx
                    Type: DeRhamComplex(Integer,[x,y,z])

  dy : der := generator(2)
   dy
                    Type: DeRhamComplex(Integer,[x,y,z])

  dz : der := generator(3)
   dz
                    Type: DeRhamComplex(Integer,[x,y,z])
```

This is an alternative way to give the above assignments.

```
  [dx,dy,dz] := [generator(i)$der for i in 1..3]
    [dx,dy,dz]
                    Type: List DeRhamComplex(Integer,[x,y,z])
```

Now we define some one-forms.

```
  alpha : der := f*dx + g*dy + h*dz
          3   2                   2     3 2       2
     (- 2x y z  + x y z)dz + (- 7z sin(x y ) + y z cos(z))dy
   +
          3 2 5    2
     (- 5x y z  + x y z)dx
                    Type: DeRhamComplex(Integer,[x,y,z])

  beta  : der := cos(tan(x*y*z)+x*y*z)*dx + x*dy
    x dy + cos(tan(x y z) + x y z)dx
                    Type: DeRhamComplex(Integer,[x,y,z])
```

A well-known theorem states that the composition of exteriorDifferential with itself is the zero map for continuous forms. Let's verify this theorem for alpha.

```
  exteriorDifferential alpha
         2                 3 2                    3 2
     (y z sin(z) + 14z sin(x y ) - 2y z cos(z) - 2x z  + x z)dy dz
   +
         3 2 4     2   2          2
     (25x y z  - 6x y z  + y z - x y)dx dz
   +
           2 2 2     3 2       3   5    2
     (- 21x y z cos(x y ) + 10x y z  - x z)dx dy
                     Type: DeRhamComplex(Integer,[x,y,z])
```

We see a lengthy output of the last expression, but nevertheless, the composition is zero.

```
  exteriorDifferential %
```

```
   0
                    Type: DeRhamComplex(Integer,[x,y,z])
```

Now we check that exteriorDifferential is a "graded derivation" D,
that is, D satisfies:

```
  D(a*b) = D(a)*b + (-1)**degree(a)*a*D(b)
```

```
  gamma := alpha * beta
        4   2    2               3   2
     (2x y z  - x y z)dy dz + (2x y z  - x y z)cos(tan(x y z) + x y z)dx dz
   +
       2     3 2       2                                    4 2 5    3
    ((7z sin(x y ) - y z cos(z))cos(tan(x y z) + x y z) - 5x y z  + x y z)dx dy
                    Type: DeRhamComplex(Integer,[x,y,z])
```

We try this for the one-forms alpha and beta.

```
  exteriorDifferential(gamma) - (exteriorDifferential(alpha)*beta - alpha * exteriorDifferential(beta))
    0
                    Type: DeRhamComplex(Integer,[x,y,z])
```

Now we define some "basic operators"

```
  a : BOP := operator('a)
    a
                    Type: BasicOperator
```

```
  b : BOP := operator('b)
    b
                    Type: BasicOperator
```

```
  c : BOP := operator('c)
    c
                    Type: BasicOperator
```

We also define some indeterminate one- and two-forms using these
operators.

```
  sigma := a(x,y,z) * dx + b(x,y,z) * dy + c(x,y,z) * dz
    c(x,y,z)dz + b(x,y,z)dy + a(x,y,z)dx
                    Type: DeRhamComplex(Integer,[x,y,z])
```

```
  theta  := a(x,y,z) * dx * dy + b(x,y,z) * dx * dz + c(x,y,z) * dy * dz
    c(x,y,z)dy dz + b(x,y,z)dx dz + a(x,y,z)dx dy
                    Type: DeRhamComplex(Integer,[x,y,z])
```

This allows us to get formal definitions for the "gradient" ...

```
  totalDifferential(a(x,y,z))$der
```

```
   (23)  a  (x,y,z)dz + a  (x,y,z)dy + a  (x,y,z)dx
          ,3             ,2             ,1
                      Type: DeRhamComplex(Integer,[x,y,z])
```

the "curl" ...

```
  exteriorDifferential sigma
     (c  (x,y,z) - b  (x,y,z))dy dz + (c  (x,y,z) - a  (x,y,z))dx dz
       ,2           ,3                  ,1           ,3
   +
     (b  (x,y,z) - a  (x,y,z))dx dy
       ,1           ,2
                      Type: DeRhamComplex(Integer,[x,y,z])
```

and the "divergence."

```
  exteriorDifferential theta
    (c  (x,y,z) - b  (x,y,z) + a  (x,y,z))dx dy dz
      ,1           ,2           ,3
                      Type: DeRhamComplex(Integer,[x,y,z])
```

Note that the De Rham complex is an algebra with unity. This element 1 is the basis for elements for zero-forms, that is, functions in our space.

```
  one : der := 1
    1
                      Type: DeRhamComplex(Integer,[x,y,z])
```

To convert a function to a function lying in the De Rham complex, multiply the function by "one."

```
  g1 : der := a([x,t,y,u,v,z,e]) * one
    a(x,t,y,u,v,z,e)
                      Type: DeRhamComplex(Integer,[x,y,z])
```

A current limitation of Axiom forces you to write functions with more than four arguments using square brackets in this way.

```
  h1 : der := a([x,y,x,t,x,z,y,r,u,x]) * one
    a(x,y,x,t,x,z,y,r,u,x)
                       Type: DeRhamComplex(Integer,[x,y,z])
```

Now note how the system keeps track of where your coordinate functions are located in expressions.

```
  exteriorDifferential g1
    a  (x,t,y,u,v,z,e)dz + a  (x,t,y,u,v,z,e)dy + a  (x,t,y,u,v,z,e)dx
     ,6                     ,3                     ,1
                      Type: DeRhamComplex(Integer,[x,y,z])
```

```
  exteriorDifferential h1
     a  (x,y,x,t,x,z,y,r,u,x)dz
      ,6
   +
     (a  (x,y,x,t,x,z,y,r,u,x) + a  (x,y,x,t,x,z,y,r,u,x))dy
       ,7                          ,2
   +
         a   (x,y,x,t,x,z,y,r,u,x) + a  (x,y,x,t,x,z,y,r,u,x)
          ,10                         ,5
       +
         a  (x,y,x,t,x,z,y,r,u,x) + a  (x,y,x,t,x,z,y,r,u,x)
          ,3                         ,1
    *
       dx
                        Type: DeRhamComplex(Integer,[x,y,z])
```

In this example of Euclidean three-space, the basis for the De Rham complex consists of the eight forms: 1, dx, dy, dz, dx*dy, dx*dz, dy*dz, and dx*dy*dz.

```
  coefficient(gamma, dx*dy)
       2     3 2       2                                    4 2 5    3
    (7z sin(x y ) - y z cos(z))cos(tan(x y z) + x y z) - 5x y z  + x y z
                        Type: Expression Integer

  coefficient(gamma, one)
    0
                        Type: Expression Integer

  coefficient(g1,one)
    a(x,t,y,u,v,z,e)
                        Type: Expression Integer
```

DirectProduct examples
=====================================================================

This type represents the finite direct or cartesian product of an
underlying component type. This contrasts with simple vectors in that
the members can be viewed as having constant length. Thus many
categorical properties can by lifted from the underlying component
type.  Component extraction operations are provided but no updating
operations.  Thus new direct product elements can either be created by
converting vector elements using the directProduct function or by
taking appropriate linear combinations of basis vectors provided by
the unitVector operation.

domain DIRRING DirichletRing

The Dirichlet Ring is the ring of arithmetical functions

$$f : \mathbb{N}_+ \to R$$

(see `http://en.wikipedia.org/wiki/Arithmetic_function`) together with the Dirichlet convolution (see `http://en.wikipedia.org/wiki/Dirichlet_convolution`) as multiplication and component-wise addition. Since we can consider the values an arithmetic functions assumes as the coefficients of a Dirichlet generating series, we call R the coefficient ring of a function.

In general we only assume that the coefficient ring R is a ring. If R happens to be commutative, then so is the Dirichlet ring, and in this case it is even an algebra.

Apart from the operations inherited from those categories, we only provide some convenient coercion functions.

====================================================================
MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
====================================================================

DistributedMultivariatePolynomial which is abbreviated as DMP and
HomogeneousDistributedMultivariatePolynomial, which is abbreviated
as HDMP, are very similar to MultivariatePolynomial except that
they are represented and displayed in a non-recursive manner.

  (d1,d2,d3) : DMP([z,y,x],FRAC INT)
                      Type: Void

The constructor DMP orders its monomials lexicographically while
HDMP orders them by total order refined by reverse lexicographic
order.

  d1 := -4*z + 4*y**2*x + 16*x**2 + 1
            2       2
   - 4z + 4y x + 16x  + 1
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)
```

```
  d2 := 2*z*y**2 + 4*x + 1
       2
   2z y  + 4x + 1
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

  d3 := 2*z*x**2 - 2*y**2 - x
       2     2
   2z x  - 2y  - x
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)
```

These constructors are mostly used in Groebner basis calculations.

```
  groebner [d1,d2,d3]
        1568  6   1264  5    6   4   182  3   2047  2    103      2857
   [z - ---- x  - ---- x  + --- x  + --- x  - ---- x  - ---- x - -----,
        2745       305       305       549       610      2745     10980

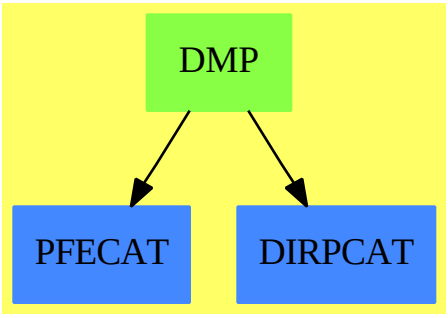
       2
    2z y  + 4x + 1
 Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)

  n3 := d3
       2     2
    2z x  - 2y  - x
 Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)
```

Note that we get a different Groebner basis when we use the HDMP polynomials, as expected.



```
  groebner [n1,n2,n3]
     4     3   3  2   1     1   4   29  3   1  2   7        9     1
   [y  + 2x  - - x  + - z - -, x  + -- x  - - y  - - z x - -- x - -,
              2      2     8        4      8      4       16     4
       2        1   2      2       1     2    2   1
```

```
   z y  + 2x + -, y x + 4x  - z + -, z x  - y  - - x,
              2                 4             2
    2     2     2   1     3
   z  - 4y  + 2x  - - z - - x]
                   4     2
     Type: List HomogeneousDistributedMultivariatePolynomial([z,y,x],
                                                        Fraction Integer)
```

```
GeneralDistributedMultivariatePolynomial is somewhat more flexible in
the sense that as well as accepting a list of variables to specify the
variable ordering, it also takes a predicate on exponent vectors to
specify the term ordering.  With this polynomial type the user can
experiment with the effect of using completely arbitrary term orderings.
This flexibility is mostly important for algorithms such as Groebner
basis calculations which can be very sensitive to term ordering.

— domain DMP DistributedMultivariatePolynomial —

```
)abbrev domain DMP DistributedMultivariatePolynomial
++ Author: Barry Trager
++ Description:
++ This type supports distributed multivariate polynomials
++ whose variables are from a user specified list of symbols.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.
++ The term ordering is lexicographic specified by the variable
++ list parameter with the most significant variable first in the list.

DistributedMultivariatePolynomial(vl,R): public == private where
  vl : List Symbol
  R  : Ring
  E   ==> DirectProduct(#vl,NonNegativeInteger)
  OV  ==> OrderedVariableList(vl)
  public == PolynomialCategory(R,E,OV) with
      reorder: (%,List Integer) -> %
```

```
        ++ reorder(p, perm) applies the permutation perm to the variables
        ++ in a polynomial and returns the new correctly ordered polynomial

domain DFLOAT DoubleFloat

Greg Vanuxem has added some functionality to allow the user to modify the printed format of floating point numbers. The format of the numbers follows the common lisp format specification for floats. First we include Greg's email to show the use of this feature:

```
PS: For those who use the Doublefloat domain
    there is an another (undocumented) patch that adds a
    lisp format to the DoubleFloat output routine. Copy
    int/algebra/DFLOAT.spad to your working directory,
    patch it, compile it and ")lib" it when necessary.
```

```
(1) -> )boot $useBFasDefault:=false

(SPADLET |$useBFasDefault| NIL)
Value = NIL
(1) -> a:= matrix [ [0.5978,0.2356], [0.4512,0.2355] ]

        +      0.5978               0.2356       +
   (1)  |                                        |
        +0.45119999999999999  0.23549999999999999+
                              Type: Matrix DoubleFloat
(2) -> )lib DFLOAT
   DoubleFloat is now explicitly exposed in frame initial
   DoubleFloat will be automatically loaded when needed
from /home/greg/Axiom/DFLOAT.nrlib/code
(2) -> doubleFloatFormat("~,4,,F")

   (2)  "~G"
                              Type: String
(3) -> a

        +0.5978  0.2356+
   (3)  |              |
        +0.4512  0.2355+
                              Type: Matrix DoubleFloat
```

So it is clear that he has added a new function called `doubleFloatFormat` which takes a string argument that specifies the common lisp format control string (¨~,4,,F¨). For reference we quote from the common lisp manual [**?**]. On page 582 we find:

> A format directive consists of a tilde (~), optional prefix parameters separated by commas, optional colon (:) and at-sign (@) modifiers, and a single character indicating what kind of directive this is. The alphabetic case of the directive character is ignored. The prefix parameters are generally integers, notated as optionally signed decimal numbers.
>
> X3J13 voted in June 1987 (80) to specify that if both colon and at-sign modifiers are present, they may appear in either order; thus ~:@R and ~@:R mean the same thing. However, it is traditional to put the colon first, and all examples in the book put colon before at-signs.

On page 588 we find:

> ~F
>
> *Fixed-format floating-point.* The next *arg* is printed as a floating point number.
>
> The full form is ~*w*,*d*,*k*,*overfowchar*,*padchar*F. The parameter *w* is the width of the filed to be printed; *d* is the number of digits to print after the decimal point; *k* is a scale factor that defaults to zero.

Exactly *w* characters will be output. First, leading copies of the character *padchar* (which defaults to a space) are printed, if necessary, to pad the field on the left. If the *arg* is negative, then a minus sign is printed; if the *arg* is not negative, then a plus signed is printed if and only if the @ modifier was specified. Then a sequence of digits, containing a single embedded decimal point, is printed; this represents the magnitude of the value of *arg* times 10^k, rounded to *d* fractional digits. (When rounding up and rounding down would produce printed values equidistant from the scaled value of *arg*, then the implementation is free to use either one. For example, printing the argument 6.375 using the format ~4.2F may correctly produce either 6.37 or 6.38.) Leading zeros are not permitted, except that a single zero digit is output before the decimal point if the printed value is less than 1, and this single zero digit is not output after all if $w = d + 1$.

If it is impossible to print the value in the required format in the field of width *w*, then one of two actions is taken. If the parameter *overflowchar* is specified, then *w* copies of that parameter are printed instead of the scaled value of *arg*. If the *overflowchar* parameter is omitted, then the scaled value is printed using more than *w* characters, as many more as may be needed.

If the *w* parameter is omitted, then the field is of variable width. In effect, a value is chosen for *w* in such a way that no leading pad characters need to be printed and exactly *d* characters will follow the decimal point. For example, the directive ~,2F will print exactly two digits after the decimal point and as many as necessary before the decimal point.

If the parameter *d* is omitted, then there is no constraint on the number of digits to appear after the decimal point. A value is chosen for *d* in such a way that as many digits as possible may be printed subject to the width constraint imposed by the parameter *w* and the constraint that no trailing zero digits may appear in the fraction, except that if the fraction to be printed is zero, then a single zero digit should appear after the decimal point if permitted by the width constraint.

If both *w* and *d* are omitted, then the effect is to print the value using ordinary free-format output; `prin1` uses this format for any number whose magnitude is either zero or between 10^{-3} (inclusive) and 10^7 (exclusive).

If *w* is omitted, then if the magnitude of *arg* is so large (or, if *d* is also omitted, so small) that more than 100 digits would have to be printed, then an implementation is free, at its discretion, to print the number using exponential notation instead, as if by the directive ~E (with all parameters of ~E defaulted, not taking their valued from the ~F directive).

If *arg* is a rational number, then it is coerced to be a `single-float` and then printed. (Alternatively, an implementation is permitted to process a rational number by any other method that has essentially the same behavior but avoids such hazards as loss of precision or overflow because of the coercion. However, note that if *w* and *d* are unspecified and the number has no exact decimal representation, for example 1/3, some precision cutoff must be chosen by the implementation; only a finite number of digits may be printed.)

If *arg* is a complex number or some non-numeric object, then it is printed using the format directive ~*w*D, thereby printing it in decimal radix and a minimum field width of *w*. (If it is desired to print each of the real part and imaginary part of a complex number using a ~F directive, then this must be done explicitly with two ~F directives and code to extract the two parts of the complex number.)

A key difficulty is creating test suites which generate DoubleFloats. We need to be bit-exact in the results. This can be achieved using the common lisp `integer-decode-float` function. We cover that function in two different ways, with `machineFraction` which translates the results into an Axiom **Fraction(Integer)** and `integerDecode` which just returns a list of the multiple values from the `integer-decode-float` function.

====================================================================
DoubleFloat examples
====================================================================

Axiom provides two kinds of floating point numbers.  The domain Float
(abbreviation FLOAT) implements a model of arbitrary precision
floating point numbers.  The domain DoubleFloat (abbreviation DFLOAT)
is intended to make available hardware floating point arithmetic in
Axiom.  The actual model of floating point DoubleFloat that provides
is system-dependent.  For example, on the IBM system 370 Axiom uses
IBM double precision which has fourteen hexadecimal digits of
precision or roughly sixteen decimal digits.  Arbitrary precision
floats allow the user to specify the precision at which arithmetic
```

```
operations are computed.  Although this is an attractive facility, it
comes at a cost. Arbitrary-precision floating-point arithmetic
typically takes twenty to two hundred times more time than hardware
floating point.

The usual arithmetic and elementary functions are available for
DoubleFloat.  By default, floating point numbers that you enter into
Axiom are of type Float.

  2.71828
   2.71828
                      Type: Float

You must therefore tell Axiom that you want to use DoubleFloat values
and operations.  The following are some conservative guidelines for
getting Axiom to use DoubleFloat.

To get a value of type DoubleFloat, use a target with @, ...

  2.71828@DoubleFloat
   2.71828
                      Type: DoubleFloat

a conversion, ...

  2.71828 :: DoubleFloat
   2.71828
                      Type: DoubleFloat

or an assignment to a declared variable.  It is more efficient if you
use a target rather than an explicit or implicit conversion.

  eApprox : DoubleFloat := 2.71828
   2.71828
                      Type: DoubleFloat

You also need to declare functions that work with DoubleFloat.

  avg : List DoubleFloat -> DoubleFloat
                      Type: Void

  avg l ==
    empty? l => 0 :: DoubleFloat
    reduce(_+,l) / #l
                      Type: Void

  avg []
   0.
                      Type: DoubleFloat
```

```
  avg [3.4,9.7,-6.8]
   2.1000000000000001
                      Type: DoubleFloat
```

```
Use package-calling for operations from DoubleFloat unless the
arguments themselves are already of type DoubleFloat.
```

```
  cos(3.1415926)$DoubleFloat
   -0.99999999999999856
                      Type: DoubleFloat

  cos(3.1415926 :: DoubleFloat)
   -0.99999999999999856
                      Type: DoubleFloat
```

```
By far, the most common usage of DoubleFloat is for functions to be
graphed.

You can get the exact machine-specific bits of a DoubleFloat in two ways.
The first is to use the integerDecode function to break the DoubleFloat
into components.
```

```
  a := -1.0/3.0

    -0.33333333333333331

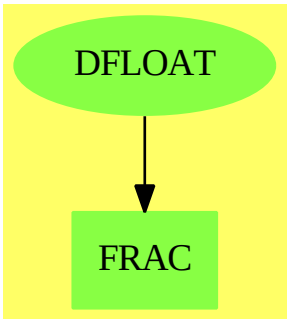
  integerDecode a

    [6004799503160661,- 54,- 1]
```

```
This is the mantissa, exact to 54 bits, the power of 2, and the sign.
Thus it is:
```

```
    6004799503160661 * 2^-54
```

```
You can get the same information as a fraction with
```



```
   machineFraction a

     6004799503160661
  - ------------------
    18014398509481984
```

```
where the denominator 18014398509481984 is 2^54

— domain DFLOAT DoubleFloat —

```
)abbrev domain DFLOAT DoubleFloat
++ Author: Michael Monagan
++ Date Created: January 1988
++ Description:
++ \spadtype{DoubleFloat} is intended to make accessible
++ hardware floating point arithmetic in Axiom, either native double
++ precision, or IEEE. On most machines, there will be hardware support for
++ the arithmetic operations: ++ +, *, / and possibly also the
++ sqrt operation.
++ The operations exp, log, sin, cos, atan are normally coded in
++ software based on minimax polynomial/rational approximations.
++
```

```
++ Some general comments about the accuracy of the operations:
++ the operations +, *, / and sqrt are expected to be fully accurate.
++ The operations exp, log, sin, cos and atan are not expected to be
++ fully accurate.  In particular, sin and cos
++ will lose all precision for large arguments.
++
++ The Float domain provides an alternative to the DoubleFloat domain.
++ It provides an arbitrary precision model of floating point arithmetic.
++ This means that accuracy problems like those above are eliminated
++ by increasing the working precision where necessary.  \spadtype{Float}
++ provides some special functions such as erf, the error function
++ in addition to the elementary functions.  The disadvantage of Float is that
++ it is much more expensive than small floats when the latter can be used.

DoubleFloat(): Join(FloatingPointSystem, DifferentialRing, OpenMath,
   TranscendentalFunctionCategory, SpecialFunctionCategory, _
   ConvertibleTo InputForm) with

      _/   : (%, Integer) -> %
        ++ x / i computes the division from x by an integer i.

      _*_* : (%,%) -> %
        ++ x ** y returns the yth power of x (equal to \spad{exp(y log x)}).

      exp1 : () -> %
        ++ exp1() returns the natural log base \spad{2.718281828...}.

      hash : % -> Integer
        ++ hash(x) returns the hash key for x

      log2 :  % -> %
        ++ log2(x) computes the logarithm with base 2 for x.

      log10: % -> %
        ++ log10(x) computes the logarithm with base 10 for x.

      atan : (%,%) -> %
        ++ atan(x,y) computes the arc tangent from x with phase y.

      Gamma: % -> %
        ++ Gamma(x) is the Euler Gamma function.

      Beta : (%,%) -> %
        ++ Beta(x,y) is \spad{Gamma(x) * Gamma(y)/Gamma(x+y)}.

      doubleFloatFormat : String -> String
        ++doubleFloatFormat changes the output format for doublefloats
        ++using lisp format strings

      rationalApproximation: (%, NonNegativeInteger) -> Fraction Integer
```

```
        ++rationalApproximation(f, n) computes a rational approximation
        ++r to f with relative error \spad{< 10**(-n)}.

      rationalApproximation: (%, NonNegativeInteger, NonNegativeInteger) -> _
           Fraction Integer
        ++rationalApproximation(f, n, b) computes a rational
        ++approximation r to f with relative error \spad{< b**(-n)}
        ++(that is, \spad{|(r-f)/f| < b**(-n)}).

      machineFraction : % -> Fraction Integer
        ++machineFraction(x) returns a bit-exact fraction of the machine
        ++floating point number using the common lisp integer-decode-float
        ++function. See Steele, ISBN 0-13-152414-3 p354
        ++This function can be used to print results which do not depend
        ++on binary-to-decimal conversions
        ++
        ++X a:DFLOAT:=-1.0/3.0
        ++X machineFraction a

      integerDecode : % -> List Integer
        ++integerDecode(x) returns the multiple values of the  common
        ++lisp integer-decode-float function.
        ++See Steele, ISBN 0-13-152414-3 p354. This function can be used
        ++to ensure that the results are bit-exact and do not depend on
        ++the binary-to-decimal conversions.
        ++
        ++X a:DFLOAT:=-1.0/3.0
        ++X integerDecode a

====================================================================
DoubleFloatMatrix examples
====================================================================
This domain creates a lisp simple array of machine doublefloats.
It provides one new function called qnew which takes an integer
that gives the array length.

NOTE: Unlike normal Axiom arrays the DoubleFloatMatrix arrays
are 0-based so the first element is 0. Axiom arrays normally
start at 1.

a:DFMAT:=qnew(2,3)

      ++ sinh(z) returns the hyperbolic sine of a Puiseux series z.
    cosh: UPXS -> UPXS
      ++ cosh(z) returns the hyperbolic cosine of a Puiseux series z.
    tanh: UPXS -> UPXS
      ++ tanh(z) returns the hyperbolic tangent of a Puiseux series z.
    coth: UPXS -> UPXS
      ++ coth(z) returns the hyperbolic cotangent of a Puiseux series z.
    sech: UPXS -> UPXS
      ++ sech(z) returns the hyperbolic secant of a Puiseux series z.
    csch: UPXS -> UPXS
      ++ csch(z) returns the hyperbolic cosecant of a Puiseux series z.

--% ArcHyperbolicFunctionCategory

    asinh: UPXS -> UPXS
      ++ asinh(z) returns the inverse hyperbolic sine of a Puiseux series z.
    acosh: UPXS -> UPXS
      ++ acosh(z) returns the inverse hyperbolic cosine of a Puiseux series z.
    atanh: UPXS -> UPXS
      ++ atanh(z) returns the inverse hyperbolic tangent of a Puiseux series z.
    acoth: UPXS -> UPXS
      ++ acoth(z) returns the inverse hyperbolic cotangent
      ++ of a Puiseux series z.
    asech: UPXS -> UPXS
      ++ asech(z) returns the inverse hyperbolic secant of a Puiseux series z.
    acsch: UPXS -> UPXS
      ++ acsch(z) returns the inverse hyperbolic cosecant
      ++ of a Puiseux series z.

— Equation.help —

```
========================================================================
Equation examples
========================================================================

The Equation domain provides equations as mathematical objects.  These
are used, for example, as the input to various solve operations.

Equations are created using the equals symbol, =.

  eq1 := 3*x + 4*y = 5
   4y + 3x= 5
                         Type: Equation Polynomial Integer

  eq2 := 2*x + 2*y = 3
   2y + 2x= 3
                         Type: Equation Polynomial Integer

The left- and right-hand sides of an equation are accessible using
the operations lhs and rhs.

  lhs eq1
   4y + 3x
                         Type: Polynomial Integer

  rhs eq1
   5
                         Type: Polynomial Integer

Arithmetic operations are supported and operate on both sides of the
equation.

  eq1 + eq2
   6y + 5x= 8
```

```
                        Type: Equation Polynomial Integer

  eq1 * eq2
     2             2
   8y  + 14x y + 6x = 15
                        Type: Equation Polynomial Integer

  2*eq2 - eq1
   x= 1
                        Type: Equation Polynomial Integer
```

Equations may be created for any type so the arithmetic operations
will be defined only when they make sense. For example, exponentiation
is not defined for equations involving non-square matrices.

```
  eq1**2
      2             2
   16y  + 24x y + 9x = 25
                         Type: Equation Polynomial Integer
```

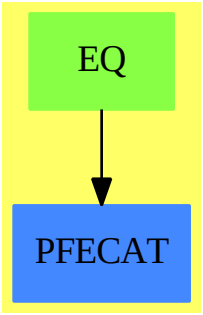
Note that an equals symbol is also used to test for equality of values
in certain contexts. For example, x+1 and y are unequal as polynomials.

```
  if x+1 = y then "equal" else "unequal"
   "unequal"
                          Type: String

  eqpol := x+1 = y
   x + 1= y
                          Type: Equation Polynomial Integer
```

If an equation is used where a Boolean value is required, then
it is evaluated using the equality test from the operand type.

```
  if eqpol then "equal" else "unequal"
   "unequal"
                          Type: String
```



If one wants a Boolean value rather than an equation, all one has to
do is ask!

```
  eqpol::Boolean
   false
                          Type: Boolean
```

--FOR THE BENEFIT  OF LIBAXO GENERATION
++ Author: Stephen M. Watt, enhancements by Johannes Grabmeier
++ Date Created: April 1985
++ Date Last Updated: June 3, 1991; September 2, 1992
++ Description:
++ Equations as mathematical objects.  All properties of the basis domain,
++ e.g. being an abelian group are carried over the equation domain, by
++ performing the structural operations on the left and on the
++ right hand side.
--   The interpreter translates "=" to "equation".  Otherwise, it will
--   find a modemap for "=" in the domain of the arguments.

Equation(S: Type): public == private where
  Ex ==> OutputForm
  public ==> Type with
    "=": (S, S) -> $
        ++ a=b creates an equation.
    equation: (S, S) -> $
        ++ equation(a,b) creates an equation.
```

```
swap: $ -> $
    ++ swap(eq) interchanges left and right hand side of equation eq.
lhs: $ -> S
    ++ lhs(eqn) returns the left hand side of equation eqn.
rhs: $ -> S
    ++ rhs(eqn) returns the right hand side of equation eqn.
map: (S -> S, $) -> $
    ++ map(f,eqn) constructs a new equation by applying f to both
    ++ sides of eqn.

=====================================================================
EqTable examples
=====================================================================

The EqTable domain provides tables where the keys are compared using
eq?.  Keys are considered equal only if they are the same instance of
a structure.  This is useful if the keys are themselves updatable
structures.  Otherwise, all operations are the same as for type Table.

The operation table is here used to create a table where the keys are
lists of integers.

  e: EqTable(List Integer, Integer) := table()
   table()
                    Type: EqTable(List Integer,Integer)

These two lists are equal according to =, but not according to eq?.

  l1 := [1,2,3]
   [1,2,3]
                    Type: List PositiveInteger

  l2 := [1,2,3]
   [1,2,3]
                    Type: List PositiveInteger
Because the two lists are not eq?, separate values can be stored under
each.

  e.l1 := 111
   111
                    Type: PositiveInteger

  e.l2 := 222
```

```
   222
                    Type: PositiveInteger

  e.11
   111
                    Type: PositiveInteger

====================================================================
Exit examples
====================================================================

A function that does not return directly to its caller has Exit as its
return type.  The operation error is an example of one which does not
return to its caller.  Instead, it causes a return to top-level.

  n := 0

The function gasp is given return type Exit since it is guaranteed
never to return a value to its caller.

  gasp(): Exit ==
    free n
    n := n + 1
    error "Oh no!"

The return type of half is determined by resolving the types of the
two branches of the if.

  half(k) ==
    if odd? k then gasp()
    else k quo 2

Because gasp has the return type Exit, the type of if in half is
resolved to be Integer.

  half 4

=====================================================================
Expression examples
=====================================================================

Expression is a constructor that creates domains whose objects
can have very general symbolic forms.  Here are some examples:

This is an object of type Expression Integer.

  sin(x) + 3*cos(x)**2

This is an object of type Expression Float.

  tan(x) - 3.45*x

This object contains symbolic function applications, sums,
products, square roots, and a quotient.
```

```
  (tan sqrt 7 - sin sqrt 11)**2 / (4 - cos(x - y))
```

As you can see, Expression actually takes an argument domain. The coefficients of the terms within the expression belong to the argument domain. Integer and Float, along with Complex Integer and Complex Float are the most common coefficient domains.

The choice of whether to use a Complex coefficient domain or not is important since Axiom can perform some simplifications on real-valued objects

```
  log(exp  x)@Expression(Integer)
```

... which are not valid on complex ones.

```
  log(exp  x)@Expression(Complex Integer)
```

Many potential coefficient domains, such as AlgebraicNumber, are not usually used because Expression can subsume them.

```
  sqrt 3 + sqrt(2 + sqrt(-5))

  % :: Expression Integer
```

Note that we sometimes talk about "an object of type Expression." This is not really correct because we should say, for example, "an object of type Expression Integer" or "an object of type Expression Float." By a similar abuse of language, when we refer to an "expression" in this section we will mean an object of type Expression R for some domain R.

The Axiom documentation contains many examples of the use of Expression. For the rest of this section, we'll give you some pointers to those examples plus give you some idea of how to manipulate expressions.

It is important for you to know that Expression creates domains that have category Field. Thus you can invert any non-zero expression and you shouldn't expect an operation like factor to give you much information. You can imagine expressions as being represented as quotients of "multivariate" polynomials where the "variables" are kernels. A kernel can either be a symbol such as x or a symbolic function application like sin(x + 4). The second example is actually a nested kernel since the argument to sin contains the kernel x.

```
  height mainKernel sin(x + 4)
```

Actually, the argument to sin is an expression, and so the structure of Expression is recursive. See Kernel which demonstrates how to

```
extract the kernels in an expression.

Use the HyperDoc Browse facility to see what operations are applicable
to expression.  At the time of this writing, there were 262 operations
with 147 distinct name in Expression Integer.  For example, numer and
denom extract the numerator and denominator of an expression.

  e := (sin(x) - 4)**2 / ( 1 - 2*y*sqrt(- y) )

  numer e

  denom e

Use D to compute partial derivatives.

  D(e, x)

  D(e, [x, y], [1, 2])

When an expression involves no ‘‘symbol kernels’’ (for example, x), it
may be possible to numerically evaluate the expression.

If you suspect the evaluation will create a complex number, use
complexNumeric.

  complexNumeric(cos(2 - 3*%i))

If you know it will be real, use numeric.

  numeric(tan 3.8)

The numeric operation will display an error message if the evaluation
yields a calue with an non-zero imaginary part.  Both of these
operations have an optional second argument n which specifies that the
accuracy of the approximation be up to n decimal places.

When an expression involves no "symbolic application" kernels, it
may be possible to convert it a polynomial or rational function in the
variables that are present.

  e2 := cos(x**2 - y + 3)

  e3 := asin(e2) - %pi/2

  e3 :: Polynomial Integer

This also works for the polynomial types where specific variables
and their ordering are given.

  e3 :: DMP([x, y], Integer)
```

```
Finally, a certain amount of simplication takes place as expressions
are constructed.

  sin %pi

  cos(%pi / 4)

For simplications that involve multiple terms of the expression, use
simplify.

  tan(x)**6 + 3*tan(x)**4 + 3*tan(x)**2 + 1

  simplify %

=====================================================================
ExponentialOfUnivariatePuiseuxSeries examples
=====================================================================
```

```
ExponentialOfUnivariatePuiseuxSeries is a domain used to represent
essential singularities of functions.  An object in this domain is a
function of the form exp(f(x)), where f(x) is a Puiseux series with no
terms of non-negative degree.  Objects are ordered according to order of
singularity, with functions which tend more rapidly to zero or infinity
considered to be larger.  Thus, if order(f(x)) < order(g(x)), i.e. the
first non-zero term of f(x) has lower degree than the first non-zero
term of g(x), then exp(f(x)) > exp(g(x)). If order(f(x)) = order(g(x)),
then the ordering is essentially random.  This domain is used in
computing limits involving functions with essential singularities.

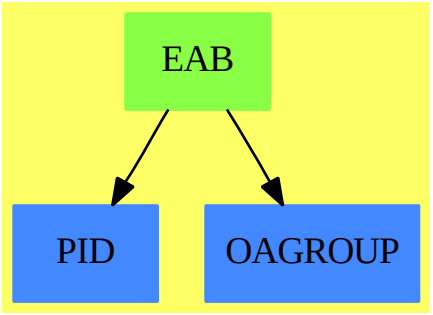
=====================================================================
ExtAlgBasis examples
=====================================================================



A domain used in the construction of the exterior algebra on a set
X over a ring R.  This domain represents the set of all ordered
subsets of the set X, assumed to be in correspondance with
{1,2,3, ...}.  The ordered subsets are themselves ordered
lexicographically and are in bijective correspondance with an ordered
basis of the exterior algebra.  In this domain we are dealing strictly
with the exponents of basis elements which can only be 0 or 1.
Thus we really have L({0,1}).

The multiplicative identity element of the exterior algebra corresponds
to the empty subset of X.  A coerce from List Integer to an
ordered basis element is provided to allow the convenient input of
expressions. Another exported function forgets the ordered structure
and simply returns the list corresponding to an ordered subset.

e04ucfAnnaType examples
=====================================================================

e04ucfAnnaType is a domain of NumericalOptimization for the NAG routine
E04UCF, a general optimization routine which can handle some singularities
in the input function.  The function measure measures the usefulness of the
routine E04UCF for the given problem. The function numericalOptimization
performs the optimization by using NagOptimisationPackage.

====================================================================
Factored examples
====================================================================

Factored creates a domain whose objects are kept in factored form as
long as possible.  Thus certain operations like * (multiplication) and
gcd are relatively easy to do.  Others, such as addition, require
somewhat more work, and the result may not be completely factored
unless the argument domain R provides a factor operation.  Each object
consists of a unit and a list of factors, where each factor consists
of a member of R (the base), an exponent, and a flag indicating what
is known about the base.  A flag may be one of "nil", "sqfr", "irred"
or "prime", which mean that nothing is known about the base, it is
square-free, it is irreducible, or it is prime, respectively.  The
current restriction to factored objects of integral domains allows
simplification to be performed without worrying about multiplication
order.

====================================================================
Decomposing Factored Objects
====================================================================

In this section we will work with a factored integer.

  g := factor(4312)
     3 2
    2 7 11
                          Type: Factored Integer

Let's begin by decomposing g into pieces.  The only possible
units for integers are 1 and -1.

  unit(g)
    1
                          Type: PositiveInteger

There are three factors.
```

```
  numberOfFactors(g)
    3
                          Type: PositiveInteger
```

We can make a list of the bases, ...

```
  [nthFactor(g,i) for i in 1..numberOfFactors(g)]
    [2,7,11]
                          Type: List Integer
```

and the exponents, ...

```
  [nthExponent(g,i) for i in 1..numberOfFactors(g)]
    [3,2,1]
                          Type: List Integer
```

and the flags. You can see that all the bases (factors) are prime.

```
  [nthFlag(g,i) for i in 1..numberOfFactors(g)]
    ["prime","prime","prime"]
                          Type: List Union("nil","sqfr","irred","prime")
```

A useful operation for pulling apart a factored object into a list
of records of the components is factorList.

```
  factorList(g)
    [[flg= "prime",fctr= 2,xpnt= 3], [flg= "prime",fctr= 7,xpnt= 2],
     [flg= "prime",fctr= 11,xpnt= 1]]
           Type: List Record(flg: Union("nil","sqfr","irred","prime"),
                             fctr: Integer,xpnt: Integer)
```

If you don't care about the flags, use factors.

```
  factors(g)
    [[factor= 2,exponent= 3],[factor= 7,exponent= 2],[factor= 11,exponent= 1]]
                          Type: List Record(factor: Integer,exponent: Integer)
```

Neither of these operations returns the unit.

```
  first(%).factor
    2
                          Type: PositiveInteger
```

```
========================================================================
Expanding Factored Objects
========================================================================
```

Recall that we are working with this factored integer.

```
  g := factor(4312)
```

```
     3 2
    2 7 11
                          Type: Factored Integer

To multiply out the factors with their multiplicities, use expand.

  expand(g)
    4312
                          Type: PositiveInteger

If you would like, say, the distinct factors multiplied together but
with multiplicity one, you could do it this way.

  reduce(*,[t.factor for t in factors(g)])
    154
                          Type: PositiveInteger

================================================================
Arithmetic with Factored Objects
================================================================

We're still working with this factored integer.

  g := factor(4312)
     3 2
    2 7 11
                          Type: Factored Integer

We'll also define this factored integer.

  f := factor(246960)
     4 2   3
    2 3 5 7
                          Type: Factored Integer

Operations involving multiplication and division are particularly
easy with factored objects.

  f * g
     7 2   5
    2 3 5 7 11
                          Type: Factored Integer

  f**500
     2000 1000 500 1500
    2    3    5   7
                          Type: Factored Integer

  gcd(f,g)
     3 2
```

```
    2 7
                        Type: Factored Integer

  lcm(f,g)
     4 2   3
    2 3 5 7 11
                        Type: Factored Integer
```

If we use addition and subtraction things can slow down because
we may need to compute greatest common divisors.

```
  f + g
     3 2
    2 7 641
                        Type: Factored Integer

  f - g
     3 2
    2 7 619
                        Type: Factored Integer
```

Test for equality with 0 and 1 by using zero? and one?, respectively.

```
  zero?(factor(0))
    true
                        Type: Boolean

  zero?(g)
    false
                        Type: Boolean

  one?(factor(1))
    true
                        Type: Boolean

  one?(f)
    false
                        Type: Boolean
```

Another way to get the zero and one factored objects is to use
package calling.

```
  0$Factored(Integer)
    0
                        Type: Factored Integer

  1$Factored(Integer)
    1
                        Type: Factored Integer
```

```
========================================================================
Creating New Factored Objects
========================================================================

The map operation is used to iterate across the unit and bases of a
factored object.

The following four operations take a base and an exponent and create a
factored object.  They differ in handling the flag component.

  nilFactor(24,2)
      2
    24
                          Type: Factored Integer

This factor has no associated information.

  nthFlag(%,1)
    "nil"
                          Type: Union("nil",...)

This factor is asserted to be square-free.

  sqfrFactor(30,2)
      2
    30
                          Type: Factored Integer

This factor is asserted to be irreducible.

  irreducibleFactor(13,10)
      10
    13
                          Type: Factored Integer

This factor is asserted to be prime.

  primeFactor(11,5)
      5
    11
                          Type: Factored Integer

A partial inverse to factorList is makeFR.

  h := factor(-720)
       4 2
    - 2 3 5
                          Type: Factored Integer

The first argument is the unit and the second is a list of records as
```

```
returned by factorList.

  h - makeFR(unit(h),factorList(h))
    0
                          Type: Factored Integer

========================================================================
Factored Objects with Variables
========================================================================

Some of the operations available for polynomials are also available
for factored polynomials.

  p := (4*x*x-12*x+9)*y*y + (4*x*x-12*x+9)*y + 28*x*x - 84*x + 63
       2            2      2                  2
    (4x  - 12x + 9)y  + (4x  - 12x + 9)y + 28x  - 84x + 63
                          Type: Polynomial Integer

  fp := factor(p)
            2  2
    (2x - 3) (y  + y + 7)
                          Type: Factored Polynomial Integer

You can differentiate with respect to a variable.

  D(p,x)
              2
    (8x - 12)y  + (8x - 12)y + 56x - 84
                          Type: Polynomial Integer

  D(fp,x)
               2
    4(2x - 3)(y  + y + 7)
                          Type: Factored Polynomial Integer

  numberOfFactors(%)
    3
                          Type: PositiveInteger

```
)abbrev domain FR Factored
++ Author: Robert S. Sutor, J. Grabmeier
++ Date Created: 1985
++ Change History: 21 Jan 1991 (J Grabmeier) 16 Aug 1994 (R S Sutor)
++ Description:
++ \spadtype{Factored} creates a domain whose objects are kept in
++ factored form as long as possible.  Thus certain operations like
++ multiplication and gcd are relatively easy to do.  Others, like
++ addition require somewhat more work, and unless the argument
++ domain provides a factor function, the result may not be
++ completely factored.  Each object consists of a unit and a list of
++ factors, where a factor has a member of R (the "base"), and
++ exponent and a flag indicating what is known about the base.  A
++ flag may be one of "nil", "sqfr", "irred" or "prime", which respectively mean
++ that nothing is known about the base, it is square-free, it is
++ irreducible, or it is prime.  The current
++ restriction to integral domains allows simplification to be
++ performed without worrying about multiplication order.
```

```

```
=====================================================================
```

```
File examples
=====================================================================

The File(S) domain provides a basic interface to read and write values
of type S in files.

Before working with a file, it must be made accessible to Axiom with
the open operation.

  ifile:File List Integer:=open("/tmp/jazz1","output")
    "jazz1"
                          Type: File List Integer

The open function arguments are a FileNam} and a String specifying the
mode.  If a full pathname is not specified, the current default
directory is assumed.  The mode must be one of "input" or "output".
If it is not specified, "input" is assumed.  Once the file has been
opened, you can read or write data.

The operations read and write are provided.

  write!(ifile, [-1,2,3])
    [- 1,2,3]
                          Type: List Integer

  write!(ifile, [10,-10,0,111])
    [10,- 10,0,111]
                          Type: List Integer

  write!(ifile, [7])
    [7]
                          Type: List Integer

You can change from writing to reading (or vice versa) by reopening a file.

  reopen!(ifile, "input")
    "jazz1"
                          Type: File List Integer

  read! ifile
    [- 1,2,3]
                          Type: List Integer

  read! ifile
    [10,- 10,0,111]
                          Type: List Integer

The read operation can cause an error if one tries to read more data
than is in the file.  To guard against this possibility the readIfCan
operation should be used.
```

```
  readIfCan! ifile
    [7]
                          Type: Union(List Integer,...)

  readIfCan! ifile
    "failed"
                          Type: Union("failed",...)
```

You can find the current mode of the file, and the file's name.

```
  iomode ifile
    "input"
                          Type: String

  name ifile
    "jazz1"
                          Type: FileName
```

When you are finished with a file, you should close it.

```
  close! ifile
    "jazz1"
                          Type: File List Integer

  )system rm /tmp/jazz1
```

A limitation of the underlying LISP system is that not all values can be represented in a file. In particular, delayed values containing compiled functions cannot be saved.

— domain FILE File —

```
)abbrev domain FILE File
++ Author: Stephen M. Watt, Victor Miller
++ Date Created: 1984
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides a basic model of files to save arbitrary values.
++ The operations provide sequential access to the contents.

File(S:SetCategory): FileCategory(FileName, S) with
        readIfCan_!: % -> Union(S, "failed")
            ++ readIfCan!(f) returns a value from the file f, if possible.
            ++ If f is not open for reading, or if f is at the end of file
            ++ then \spad{"failed"} is the result.

— FileName.help —

```
=====================================================================
FileName examples
=====================================================================

The FileName domain provides an interface to the computer's file
system.  Functions are provided to manipulate file names and to test
properties of files.

The simplest way to use file names in the Axiom interpreter is to rely
on conversion to and from strings.  The syntax of these strings
depends on the operating system.

  fn: FileName
                      Type: Void

On Linux, this is a proper file syntax:

  fn := "fname.input"
    "fname.input"
                      Type: FileName
```

```
Although it is very convenient to be able to use string notation
for file names in the interpreter, it is desirable to have a portable
way of creating and manipulating file names from within programs.

A measure of portability is obtained by considering a file name to
consist of three parts: the directory, the name, and the extension.

  directory fn
    ""
                      Type: String

  name fn
    "fname"
                      Type: String

  extension fn
    "input"
                      Type: String

The meaning of these three parts depends on the operating system.
For example, on CMS the file "SPADPROF INPUT M" would have directory
"M", name "SPADPROF" and extension "INPUT".

It is possible to create a filename from its parts.

  fn := filename("/tmp", "fname", "input")
    "/tmp/fname.input"
                      Type: FileName

When writing programs, it is helpful to refer to directories via
variables.

  objdir := "/tmp"
    "/tmp"
                      Type: String

  fn := filename(objdir, "table", "spad")
    "/tmp/table.spad"
                      Type: FileName

If the directory or the extension is given as an empty string, then
a default is used.  On AIX, the defaults are the current directory
and no extension.

  fn := filename("", "letter", "")
    "letter"
                      Type: FileName

Three tests provide information about names in the file system.
```

The exists? operation tests whether the named file exists.

```
  exists? "/etc/passwd"
    true
                      Type: Boolean
```

The operation readable? tells whether the named file can be read. If the file does not exist, then it cannot be read.

```
  readable? "/etc/passwd"
    true
                      Type: Boolean

  readable? "/etc/security/passwd"
    false
                      Type: Boolean

  readable? "/ect/passwd"
    false
                      Type: Boolean
```

Likewise, the operation writable? tells whether the named file can be written. If the file does not exist, the test is determined by the properties of the directory.

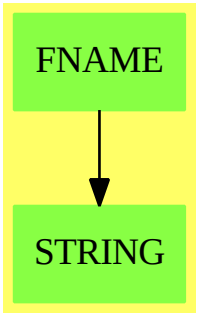
```
  writable? "/etc/passwd"
    true
                      Type: Boolean

  writable? "/dev/null"
    true
                      Type: Boolean

  writable? "/etc/DoesNotExist"
    true
                      Type: Boolean

  writable? "/tmp/DoesNotExist"
    true
                      Type: Boolean
```

The new operation constructs the name of a new writable file. The argument sequence is the same as for filename, except that the name part is actually a prefix for a constructed unique name.



The resulting file is in the specified directory with the given extension, and the same defaults are used.

```
  fn := new(objdir, "xxx", "yy")
    "/tmp/xxx1419.yy"
```

```
                    Type: FileName

=====================================================================
FiniteFieldCyclicGroup examples
```

```
================================================================

FiniteFieldCyclicGroup(p,n) implements a finite field extension of degee n
over the prime field with p elements. Its elements are represented by
powers of a primitive element, i.e. a generator of the multiplicative
(cyclic) group. As primitive element we choose the root of the extension
polynomial, which is created by createPrimitivePoly from
FiniteFieldPolynomialPackage. The Zech logarithms are stored in a table
of size half of the field size, and use SingleInteger for representing
field elements, hence, there are restrictions on the size of the field.

FiniteFieldCyclicGroupExtension examples
=======================================================================

FiniteFieldCyclicGroupExtension(GF,n)  implements a extension of degree n
over the ground field GF. Its elements are represented by powers of
a primitive element, i.e. a generator of the multiplicative (cyclic) group.
As primitive element we choose the root of the extension polynomial, which
is created by createPrimitivePoly from FiniteFieldPolynomialPackage.
Zech logarithms are stored in a table of size half of the field size,
and use SingleInteger for representing field elements, hence, there
are restrictions on the size of the field.

FiniteFieldNormalBasisExtensionByPolynomial examples
=====================================================================

FiniteFieldNormalBasisExtensionByPolynomial(GF,uni) implements a
finite extension of the ground field GF. The elements are
represented by coordinate vectors with respect to. a normal basis,
i.e. a basis consisting of the conjugates (q-powers) of an element,
in this case called normal element, where q is the size of GF.
The normal element is chosen as a root of the extension
polynomial, which MUST be normal over GF  (user responsibility)

========================================================================
FlexibleArray
========================================================================

The FlexibleArray domain constructor creates one-dimensional
arrays of elements of the same type.  Flexible arrays are an attempt
to provide a data type that has the best features of both
one-dimensional arrays (fast, random access to elements) and lists
(flexibility).  They are implemented by a fixed block of storage.
When necessary for expansion, a new, larger block of storage is
allocated and the elements from the old storage area are copied into
the new block.

Flexible arrays have available most of the operations provided by
OneDimensionalArray Vector.  Since flexible arrays are also of
category ExtensibleLinearAggregate they have operations concat!,
delete!, insert!, merge!, remove!, removeDuplicates!, and select!.  In
addition, the operations physicalLength and physicalLength! provide
user-control over expansion and contraction.

A convenient way to create a flexible array is to apply the operation
flexibleArray to a list of values.

  flexibleArray [i for i in 1..6]
    [1,2,3,4,5,6]
                      Type: FlexibleArray PositiveInteger

Create a flexible array of six zeroes.

  f : FARRAY INT := new(6,0)
    [0,0,0,0,0,0]
                      Type: FlexibleArray Integer

For i=1..6 set the i-th element to i.  Display f.

  for i in 1..6 repeat f.i := i; f
    [1,2,3,4,5,6]
                      Type: FlexibleArray Integer

Initially, the physical length is the same as the number of elements.

  physicalLength f
    6
                      Type: PositiveInteger

Add an element to the end of f.

  concat!(f,11)
    [1,2,3,4,5,6,11]
                      Type: FlexibleArray Integer
```

```
See that its physical length has grown.

  physicalLength f
    10
                    Type: PositiveInteger

Make f grow to have room for 15 elements.

  physicalLength!(f,15)
    [1,2,3,4,5,6,11]
                    Type: FlexibleArray Integer

Concatenate the elements of f to itself.  The physical length
allows room for three more values at the end.

  concat!(f,f)
    [1,2,3,4,5,6,11,1,2,3,4,5,6,11]
                    Type: FlexibleArray Integer

Use insert! to add an element to the front of a flexible array.

  insert!(22,f,1)
    [22,1,2,3,4,5,6,11,1,2,3,4,5,6,11]
                    Type: FlexibleArray Integer

Create a second flexible array from f consisting of the elements from
index 10 forward.

  g := f(10..)
    [2,3,4,5,6,11]
                    Type: FlexibleArray Integer

Insert this array at the front of f.

  insert!(g,f,1)
    [2,3,4,5,6,11,22,1,2,3,4,5,6,11,1,2,3,4,5,6,11]
                    Type: FlexibleArray Integer

Merge the flexible array f into g after sorting each in place.

  merge!(sort! f, sort! g)
    [1,1,2,2,2,2,3,3,3,3,4,4,4,4,5,5,5,5,6,6,6,6,11,11,11,11,22]
                    Type: FlexibleArray Integer

Remove duplicates in place.

  removeDuplicates! f
    [1,2,3,4,5,6,11,22]
                    Type: FlexibleArray Integer
```

```
Remove all odd integers.

  select!(i +-> even? i,f)
    [2,4,6,22]
                      Type: FlexibleArray Integer

All these operations have shrunk the physical length of f.

  physicalLength f
    8
                      Type: PositiveInteger

To force Axiom not to shrink flexible arrays call the shrinkable
operation with the argument false.  You must package call this
operation.  The previous value is returned.

  shrinkable(false)$FlexibleArray(Integer)
    true
                      Type: Boolean

— **domain FARRAY FlexibleArray** —

```
)abbrev domain FARRAY FlexibleArray
++ Author: Mark Botch
++ Description:
++ A FlexibleArray is the notion of an array intended to allow for growth
++ at the end only.  Hence the following efficient operations
++ \spad{append(x,a)} meaning append item x at the end of the array \spad{a}
++ \spad{delete(a,n)} meaning delete the last item from the array \spad{a}
++ Flexible arrays support the other operations inherited from
++ \spadtype{ExtensibleLinearAggregate}. However, these are not efficient.
++ Flexible arrays combine the \spad{O(1)} access time property of arrays
++ with growing and shrinking at the end in \spad{O(1)} (average) time.
++ This is done by using an ordinary array which may have zero or more
++ empty slots at the end.  When the array becomes full it is copied
++ into a new larger (50% larger) array.  Conversely, when the array
++ becomes less than 1/2 full, it is copied into a smaller array.
++ Flexible arrays provide for an efficient implementation of many
++ data structures in particular heaps, stacks and sets.

FlexibleArray(S: Type) == Implementation where
  ARRAYMININDEX ==> 1       -- if you want to change this, be my guest
  Implementation ==> IndexedFlexibleArray(S, ARRAYMININDEX)

domain FLOAT Float

As reported in bug number 4733 (rounding of negative numbers) errors were observed in operations such as

```
-> round(-3.9)
-> truncate(-3.9)
```

The problem is the unexpected behaviour of the shift with negative integer arguments.

```
-> shift(-7,-1)
```

returns -4 while the code here in float expects the value to be -3. shift uses the lisp function ASH 'arithmetic shift left' but the spad code expects an unsigned 'logical' shift. See

```
http://www.lispworks.com/reference/HyperSpec/Body/f_ash.htm#ash
```

A new internal function shift2 is defined in terms of shift to compensate for the use of ASH and provide the required function.

It is currently unknown whether the unexpected behaviour of shift for negative arguments will cause bugs in other parts of Axiom.

```
========================================================================
Float
========================================================================

Axiom provides two kinds of floating point numbers.  The domain Float
implements a model of arbitrary precision floating point numbers.  The
domain DoubleFloat is intended to make available hardware floating
point arithmetic in Axiom.  The actual model of floating point that
DoubleFloat provides is system-dependent.  For example, on the IBM
system 370 Axiom uses IBM double precision which has fourteen
hexadecimal digits of precision or roughly sixteen decimal digits.
Arbitrary precision floats allow the user to specify the precision at
which arithmetic operations are computed.  Although this is an
attractive facility, it comes at a cost.  Arbitrary-precision
floating-point arithmetic typically takes twenty to two hundred times
more time than hardware floating point.

========================================================================
Introduction to Float
========================================================================
```

```
Scientific notation is supported for input and output of floating
point numbers.  A floating point number is written as a string of
digits containing a decimal point optionally followed by the letter
"E", and then the exponent.

We begin by doing some calculations using arbitrary precision floats.
The default precision is twenty decimal digits.

  1.234
   1.234
                      Type: Float

A decimal base for the exponent is assumed, so the number
1.234E2 denotes 1.234x10^2.

  1.234E2
    123.4
                      Type: Float
The normal arithmetic operations are available for floating point numbers.

  sqrt(1.2 + 2.3 / 3.4 ** 4.5)
    1.0996972790 671286226
                      Type: Float

========================================================================
Conversion Functions
========================================================================

You can use conversion to go back and forth between Integer, Fraction
Integer and Float, as appropriate.

  i := 3 :: Float
    3.0
                      Type: Float

  i :: Integer
    3
                      Type: Integer

  i :: Fraction Integer
    3
                      Type: Fraction Integer

Since you are explicitly asking for a conversion, you must take
responsibility for any loss of exactness.

  r := 3/7 :: Float
    0.4285714285 7142857143
                      Type: Float
```

```
  r :: Fraction Integer
    3
    -
    7
                        Type: Fraction Integer
```

This conversion cannot be performed: use truncate or round if that is what you intend.

```
  r :: Integer
   Cannot convert from type Float to Integer for value
   0.4285714285 7142857143
```

The operations truncate and round truncate ...

```
   truncate 3.6
    3.0
                        Type: Float
```

and round to the nearest integral Float respectively.

```
  round 3.6
    4.0
                        Type: Float

  truncate(-3.6)
    - 3.0
                        Type: Float

  round(-3.6)
    - 4.0
                        Type: Float
```

The operation fractionPart computes the fractional part of x, that is, x - truncate x.

```
  fractionPart 3.6
    0.6
                        Type: Float
```

The operation digits allows the user to set the precision. It returns the previous value it was using.

```
  digits 40
    20
                        Type: PositiveInteger

  sqrt 0.2
    0.4472135954 9995793928 1834733746 2552470881
                        Type: Float
```

```
  pi()$Float
    3.1415926535 8979323846 2643383279 502884197
                        Type: Float

The precision is only limited by the computer memory available.
Calculations at 500 or more digits of precision are not difficult.

  digits 500
    40
                        Type: PositiveInteger

  pi()$Float

  3 0921861173 8193261179 3105118548 0744623799 6274956735 1885752724 891227938
  1 830119491
                        Type: Float

Reset digits to its default value.

  digits 20
    500
                        Type: PositiveInteger

Numbers of type Float are represented as a record of two
integers, namely, the mantissa and the exponent where the base of the
exponent is binary.  That is, the floating point number (m,e)
represents the number m x 2^e.  A consequence of using a binary
base is that decimal numbers can not, in general, be represented
exactly.

========================================================================
Output Functions
========================================================================

A number of operations exist for specifying how numbers of type Float
are to be displayed.  By default, spaces are inserted every ten digits
in the output for readability. Note that you cannot include spaces in
the input form of a floating point number, though you can use
underscores.

Output spacing can be modified with the outputSpacing operation.  This
inserts no spaces and then displays the value of x.

  outputSpacing 0; x := sqrt 0.2
```

```
    0.44721359549995793928
                        Type: Float

Issue this to have the spaces inserted every 5 digits.

  outputSpacing 5; x
    0.44721 35954 99957 93928
                        Type: Float

By default, the system displays floats in either fixed format
or scientific format, depending on the magnitude of the number.

  y := x/10**10
    0.44721 35954 99957 93928 E -10
                        Type: Float

A particular format may be requested with the operations
outputFloating and outputFixed.

  outputFloating(); x
    0.44721 35954 99957 93928 E 0
                        Type: Float

  outputFixed(); y
    0.00000 00000 44721 35954 99957 93928
                        Type: Float

Additionally, you can ask for n digits to be displayed after the
decimal point.

  outputFloating 2; y
    0.45 E -10
                        Type: Float

  outputFixed 2; x
    0.45
                        Type: Float

This resets the output printing to the default behavior.

========================================================================
An Example: Determinant of a Hilbert Matrix
========================================================================

Consider the problem of computing the determinant of a 10 by 10
Hilbert matrix.  The (i,j)-th entry of a Hilbert matrix is given
by 1/(i+j+1).
```

First do the computation using rational numbers to obtain the exact result.

```
  a: Matrix Fraction Integer:=matrix[ [1/(i+j+1) for j in 0..9] for i in 0..9]
         +    1   1   1   1   1   1   1   1    1+
         |1   -   -   -   -   -   -   -   -   --|
         |    2   3   4   5   6   7   8   9   10|
         |                                       |
         |1   1   1   1   1   1   1   1    1   1|
         |-   -   -   -   -   -   -   -   --  --|
         |2   3   4   5   6   7   8   9   10  11|
         |                                       |
         |1   1   1   1   1   1   1    1   1   1|
         |-   -   -   -   -   -   -   --  --  --|
         |3   4   5   6   7   8   9   10  11  12|
         |                                       |
         |1   1   1   1   1   1    1   1   1   1|
         |-   -   -   -   -   -   --  --  --  --|
         |4   5   6   7   8   9   10  11  12  13|
         |                                       |
         |1   1   1   1   1    1   1   1   1   1|
         |-   -   -   -   -   --  --  --  --  --|
         |5   6   7   8   9   10  11  12  13  14|
         |                                       |
         |1   1   1   1    1   1   1   1   1   1|
         |-   -   -   -   --  --  --  --  --  --|
         |6   7   8   9   10  11  12  13  14  15|
         |                                       |
         |1   1   1    1   1   1   1   1   1   1|
         |-   -   -   --  --  --  --  --  --  --|
         |7   8   9   10  11  12  13  14  15  16|
         |                                       |
         |1   1    1   1   1   1   1   1   1   1|
         |-   -   --  --  --  --  --  --  --  --|
         |8   9   10  11  12  13  14  15  16  17|
         |                                       |
         |1    1   1   1   1   1   1   1   1   1|
         |-   --  --  --  --  --  --  --  --  --|
         |9   10  11  12  13  14  15  16  17  18|
         |                                       |
         | 1   1   1   1   1   1   1   1   1   1|
         |--  --  --  --  --  --  --  --  --  --|
         +10  11  12  13  14  15  16  17  18  19+
                        Type: Matrix Fraction Integer
```

This version of determinant uses Gaussian elimination.

```
  d:= determinant a
                                  1
```

```
    ------------------------------------------------
    46206893947914691316295628839036278726983680000000000
                    Type: Fraction Integer

  d :: Float
    0.21641 79226 43149 18691 E -52
                    Type: Float

Now use hardware floats. Note that a semicolon (;) is used to prevent
the display of the matrix.

  b: Matrix DoubleFloat:=matrix[ [1/(i+j+1\$DoubleFloat) for j in 0..9] for i in 0..9];

                    Type: Matrix DoubleFloat

The result given by hardware floats is correct only to four
significant digits of precision.  In the jargon of numerical analysis,
the Hilbert matrix is said to be "ill-conditioned."

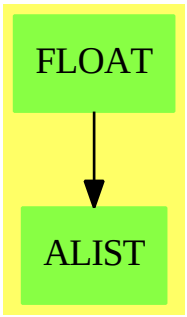
  determinant b
    2.1643677945721411E-53
                    Type: DoubleFloat

Now repeat the computation at a higher precision using Float.

  digits 40
    20
                    Type: PositiveInteger

  c: Matrix Float := matrix [ [1/(i+j+1\$Float) for j in 0..9] for i in 0..9];
                    Type: Matrix Float

  determinant c
    0.21641 79226 43149 18690 60594 98362 26174 36159 E -52
                    Type: Float



Reset digits to its default value.

  digits 20
    40
                    Type: PositiveInteger

)abbrev domain FLOAT Float

++ Author: Michael Monagan
++ Date Created:  December 1987
++ Change History: 19 Jun 1990
++ Description:
++ \spadtype{Float} implements arbitrary precision floating point arithmetic.
++ The number of significant digits of each operation can be set
++ to an arbitrary value (the default is 20 decimal digits).
++ The operation \spad{float(mantissa,exponent,base)} for integer
++ \spad{mantissa}, \spad{exponent} specifies the number
++ \spad{mantissa * base ** exponent}
++ The underlying representation for floats is binary
++ not decimal. The implications of this are described below.
++
++ The model adopted is that arithmetic operations are rounded to
++ to nearest unit in the last place, that is, accurate to within
++ \spad{2**(-bits)}. Also, the elementary functions and constants are
++ accurate to one unit in the last place.
++ A float is represented as a record of two integers, the mantissa
++ and the exponent.  The base of the representation is binary, hence
++ a \spad{Record(m:mantissa,e:exponent)} represents the number
++ \spad{m * 2 ** e}.
++ Though it is not assumed that the underlying integers are represented
++ with a binary base, the code will be most efficient when this is the
++ the case (this is true in most implementations of Lisp).
++ The decision to choose the base to be binary has some unfortunate
++ consequences.  First, decimal numbers like 0.3 cannot be represented
++ exactly.  Second, there is a further loss of accuracy during
++ conversion to decimal for output.  To compensate for this, if d digits
++ of precision are specified, \spad{1 + ceiling(log2(10^d))} bits are used.
++ Two numbers that are displayed identically may therefore be
++ not equal.  On the other hand, a significant efficiency loss would
++ be incurred if we chose to use a decimal base when the underlying
++ integer base is binary.
++
++ Algorithms used:
++ For the elementary functions, the general approach is to apply
++ identities so that the taylor series can be used, and, so
++ that it will converge within \spad{O( sqrt n )} steps.  For example,
++ using the identity \spad{exp(x) = exp(x/2)**2}, we can compute
++ \spad{exp(1/3)} to n digits of precision as follows.  We have
++ \spad{exp(1/3) = exp(2 ** (-sqrt s) / 3) ** (2 ** sqrt s)}.
++ The taylor series will converge in less than sqrt n steps and the
++ exponentiation requires sqrt n multiplications for a total of
++ \spad{2 sqrt n} multiplications.  Assuming integer multiplication costs
++ \spad{O( n**2 )} the overall running time is \spad{O( sqrt(n) n**2 )}.
```

```
++ This approach is the best known approach for precisions up to
++ about 10,000 digits at which point the methods of Brent
++ which are \spad{O( log(n) n**2 )} become competitive.  Note also that
++ summing the terms of the taylor series for the elementary
++ functions is done using integer operations.  This avoids the
++ overhead of floating point operations and results in efficient
++ code at low precisions.  This implementation makes no attempt
++ to reuse storage, relying on the underlying system to do
++ \spadgloss{garbage collection}.  I estimate that the efficiency of this
++ package at low precisions could be improved by a factor of 2
++ if in-place operations were available.
++
++ Running times: in the following, n is the number of bits of precision\br
++ \spad{*}, \spad{/}, \spad{sqrt}, \spad{pi}, \spad{exp1}, \spad{log2},
++ \spad{log10}: \spad{ O( n**2 )} \br
++ \spad{exp}, \spad{log}, \spad{sin}, \spad{atan}: \spad{O(sqrt(n) n**2)}\br
++ The other elementary functions are coded in terms of the ones above.

=====================================================================
Fraction examples
=====================================================================

The Fraction domain implements quotients.  The elements must
belong to a domain of category IntegralDomain: multiplication
must be commutative and the product of two non-zero elements must not
be zero.  This allows you to make fractions of most things you would
think of, but don't expect to create a fraction of two matrices!  The
abbreviation for Fraction is FRAC.

Use / to create a fraction.

  a := 11/12
    11
    --
    12
                    Type: Fraction Integer

  b := 23/24
    23
    --
    24
                    Type: Fraction Integer

The standard arithmetic operations are available.

  3 - a*b**2 + a + b/a
    313271
    ------
     76032
                    Type: Fraction Integer

Extract the numerator and denominator by using numer and denom,
respectively.

  numer(a)
    11
                    Type: PositiveInteger

  denom(b)
    24
                    Type: PositiveInteger

Operations like max, min, negative?, positive? and zero?
are all available if they are provided for the numerators and
denominators.

Don't expect a useful answer from factor, gcd or lcm if you apply
them to fractions.
```

```
r := (x**2 + 2*x + 1)/(x**2 - 2*x + 1)
   2
  x  + 2x + 1
  -----------
   2
  x  - 2x + 1
                Type: Fraction Polynomial Integer
```

Since all non-zero fractions are invertible, these operations have trivial definitions.

```
factor(r)
   2
  x  + 2x + 1
  -----------
   2
  x  - 2x + 1
                Type: Factored Fraction Polynomial Integer
```

Use map to apply factor to the numerator and denominator, which is probably what you mean.

```
map(factor,r)
         2
  (x + 1)
  --------
         2
  (x - 1)
                Type: Fraction Factored Polynomial Integer
```

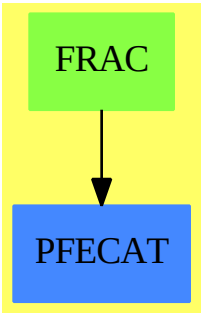
Other forms of fractions are available. Use continuedFraction to create a continued fraction.

```
continuedFraction(7/12)
    1 |     1 |     1 |     1 |
  +---+ + +---+ + +---+ + +---+
  | 1     | 1     | 2     | 2
                Type: ContinuedFraction Integer
```

Use partialFraction to create a partial fraction.

```
partialFraction(7,12)
        3   1
   1 - -- + -
        2   3
       2
                Type: PartialFraction Integer
```

Use conversion to create alternative views of fractions with objects



```
moved in and out of the numerator and denominator.

  g := 2/3 + 4/5*%i
     2   4
     - + - %i
     3   5
                    Type: Complex Fraction Integer

  g :: FRAC COMPLEX INT
    10 + 12%i
    ---------
        15
                    Type: Fraction Complex Integer

=====================================================================
FullPartialFractionExpansion expansion
=====================================================================

The domain FullPartialFractionExpansion implements factor-free
conversion of quotients to full partial fractions.

Our examples will all involve quotients of univariate polynomials
with rational number coefficients.

  Fx := FRAC UP(x, FRAC INT)
    Fraction UnivariatePolynomial(x,Fraction Integer)
                    Type: Domain

Here is a simple-looking rational function.

  f : Fx := 36 / (x**5-2*x**4-2*x**3+4*x**2+x-2)
                36
    ----------------------------
     5     4     3     2
    x  - 2x  - 2x  + 4x  + x - 2
                    Type: Fraction UnivariatePolynomial(x,Fraction Integer)

We use fullPartialFraction to convert it to an object of type
FullPartialFractionExpansion.

  g := fullPartialFraction f
      4       4        --+      - 3%A - 6
    ----- - ----- +    >        ---------
    x - 2   x + 1      --+               2
                      2          (x - %A)
                     %A  - 1= 0
Type: FullPartialFractionExpansion(Fraction Integer,
                                   UnivariatePolynomial(x,Fraction Integer))
```

Use a coercion to change it back into a quotient.

```
  g :: Fx
                36
    ----------------------------
     5     4     3     2
    x  - 2x  - 2x  + 4x  + x - 2
                  Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```

Full partial fractions differentiate faster than rational functions.

```
  g5 := D(g, 5)
        480         480         --+      2160%A + 4320
    - -------- + -------- +     >        -------------
             6           6      --+                 7
      (x - 2)     (x + 1)       2           (x - %A)
                              %A  - 1= 0
Type: FullPartialFractionExpansion(Fraction Integer,
                                   UnivariatePolynomial(x,Fraction Integer))

  f5 := D(f, 5)
                10           9            8            7            6
      - 544320x   + 4354560x  - 14696640x  + 28615680x  - 40085280x
    +
                5            4            3           2
      46656000x  - 39411360x  + 18247680x  - 5870880x  + 3317760x + 246240
  /
        20      19      18      17       16       15       14        13
      x   - 12x   + 53x   - 76x   - 159x   + 676x   - 391x   - 1596x
    +
           12        11        10        9        8        7        6        5
      2527x   + 1148x   - 4977x   + 1372x  + 4907x  - 3444x  - 2381x  + 2924x
    +
          4        3       2
      276x  - 1184x  + 208x  + 192x - 64
                     Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```

We can check that the two forms represent the same function.

```
  g5::Fx - f5
    0
                     Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```

Here are some examples that are more complicated.

```
  f : Fx := (x**5 * (x-1)) / ((x**2 + x + 1)**2 * (x-2)**3)
                  6    5
                 x  - x
    ----------------------------------
     7     6     5     3     2
```

```
   x  - 4x  + 3x  + 9x  - 6x  - 4x - 8
                  Type: Fraction UnivariatePolynomial(x,Fraction Integer)

  g := fullPartialFraction f
      1952       464        32                          179       135

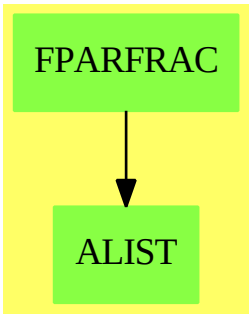
Type: FullPartialFractionExpansion(Fraction Integer,UnivariatePolynomial(x,Fraction Integer))
```

This verification takes much longer than the conversion to partial fractions.

```
  g :: Fx - f
    0
                     Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```



Use PartialFraction for standard partial fraction decompositions.

++ Description:
++ Full partial fraction expansion of rational functions

FullPartialFractionExpansion(F, UP): Exports == Implementation where
  F  : Join(Field, CharacteristicZero)
  UP : UnivariatePolynomialCategory F

  N   ==> NonNegativeInteger
  Q   ==> Fraction Integer
  O   ==> OutputForm
  RF  ==> Fraction UP
  SUP ==> SparseUnivariatePolynomial RF
  REC ==> Record(exponent: N, center: UP, num: UP)
  ODV ==> OrderlyDifferentialVariable Symbol
  ODP ==> OrderlyDifferentialPolynomial UP
  ODF ==> Fraction ODP
  FPF ==> Record(polyPart: UP, fracPart: List REC)

  Exports ==> Join(SetCategory, ConvertibleTo RF)  with
    "+":                 (UP, $) -> $
      ++ p + x returns the sum of p and x
```

```
    fullPartialFraction: RF -> $
      ++ fullPartialFraction(f) returns \spad{[p, [[j, Dj, Hj]...]]} such that
      ++ \spad{f = p(x) + sum_{[j,Dj,Hj] in l} sum_{Dj(a)=0} Hj(a)/(x - a)\^j}.
    polyPart:            $ -> UP
      ++ polyPart(f) returns the polynomial part of f.
    fracPart:            $  -> List REC
      ++ fracPart(f) returns the list of summands of the fractional part of f.
    construct:           List REC -> $
      ++ construct(l) is the inverse of fracPart.
    differentiate:       $ -> $
      ++ differentiate(f) returns the derivative of f.
    D:                    $ -> $
      ++ D(f) returns the derivative of f.
    differentiate:       ($, N) -> $
      ++ differentiate(f, n) returns the n-th derivative of f.
    D: ($, NonNegativeInteger) -> $
      ++ D(f, n) returns the n-th derivative of f.

====================================================================
MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
====================================================================

DistributedMultivariatePolynomial which is abbreviated as DMP and
HomogeneousDistributedMultivariatePolynomial, which is abbreviated
as HDMP, are very similar to MultivariatePolynomial except that
they are represented and displayed in a non-recursive manner.
```

```
  (d1,d2,d3) : DMP([z,y,x],FRAC INT)
                      Type: Void
```

The constructor DMP orders its monomials lexicographically while HDMP orders them by total order refined by reverse lexicographic order.

```
  d1 := -4*z + 4*y**2*x + 16*x**2 + 1
            2       2
   - 4z + 4y x + 16x  + 1
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

  d2 := 2*z*y**2 + 4*x + 1
       2
   2z y  + 4x + 1
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

  d3 := 2*z*x**2 - 2*y**2 - x
       2     2
   2z x  - 2y  - x
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)
```

These constructors are mostly used in Groebner basis calculations.

```
  groebner [d1,d2,d3]
        1568  6   1264  5    6   4   182  3   2047  2    103      2857

                    4     2
      Type: List HomogeneousDistributedMultivariatePolynomial([z,y,x],
                                                          Fraction Integer)
```

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term ordering.

— domain GDMP GeneralDistributedMultivariatePolynomial —

```
)abbrev domain GDMP GeneralDistributedMultivariatePolynomial
++ Author: Barry Trager
++ Description:
++ This type supports distributed multivariate polynomials
++ whose variables are from a user specified list of symbols.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.
++ The term ordering is specified by its third parameter.
++ Suggested types which define term orderings include:
++ \spadtype{DirectProduct}, \spadtype{HomogeneousDirectProduct},
++ \spadtype{SplitHomogeneousDirectProduct} and finally
++ \spadtype{OrderedDirectProduct} which accepts an arbitrary user
++ function to define a term ordering.

———-

— GeneralSparseTable.help —

```
====================================================================
GeneralSparseTable
====================================================================

Sometimes when working with tables there is a natural value to use as
the entry in all but a few cases.  The GeneralSparseTable constructor
can be used to provide any table type with a default value for
entries.

Suppose we launched a fund-raising campaign to raise fifty thousand
dollars.  To record the contributions, we want a table with strings as
keys (for the names) and integer entries (for the amount).  In a data
base of cash contributions, unless someone has been explicitly
entered, it is reasonable to assume they have made a zero dollar
contribution.

This creates a keyed access file with default entry 0.

  patrons: GeneralSparseTable(String, Integer, KeyedAccessFile(Integer), 0) := table() ;
```

```
Now patrons can be used just as any other table.  Here we record two gifts.

  patrons."Smith" := 10500

  patrons."Jones" := 22000

Now let us look up the size of the contributions from Jones and Stingy.

  patrons."Jones"

  patrons."Stingy"

Have we met our seventy thousand dollar goal?

  reduce(+, entries patrons)

So the project is cancelled and we can delete the data base:

  )system rm -r kaf*.sdata

GeneralTriangularSet examples
=====================================================================

A domain constructor of the category TriangularSetCategory.  The only
requirement for a list of polynomials to be a member of such a domain
is the following: no polynomial is constant and two distinct
polynomials have distinct main variables. Such a triangular set may
not be auto-reduced or consistent. Triangular sets are stored as
sorted lists w.r.t. the main variables of their members but they are
displayed in reverse order.

```
)abbrev domain GTSET GeneralTriangularSet
++ Author: Marc Moreno Maza (marc@nag.co.uk)
```

```
++ Date Created: 10/06/1995
++ Date Last Updated: 06/12/1996
++ References :
++  [1] P. AUBRY, D. LAZARD and M. MORENO MAZA "On the Theories
++      of Triangular Sets" Journal of Symbol. Comp. (to appear)
++ Description:
++ A domain constructor of the category \axiomType{TriangularSetCategory}.
++ The only requirement for a list of polynomials to be a member of such
++ a domain is the following: no polynomial is constant and two distinct
++ polynomials have distinct main variables. Such a triangular set may
++ not be auto-reduced or consistent. Triangular sets are stored
++ as sorted lists w.r.t. the main variables of their members but they
++ are displayed in reverse order.

    ++ domain \spadtype{GraphImage}, and sends it's data to the
    ++ viewport manager where it waits to be included in a two-dimensional
    ++ viewport window.  \spad{gi} cannot be an empty graph, and it's
    ++ elements must have been created using the \spadfun{point} or
    ++ \spadfun{component} functions, not by a previous
    ++ \spadfun{makeGraphImage}.
  makeGraphImage  :  (L L P)                                   -> $
    ++ makeGraphImage(llp) returns a graph of the domain
    ++ \spadtype{GraphImage} which is composed of the points and
    ++ lines from the list of lists of points, \spad{llp}, with
    ++ default point size and default point and line colours. The graph
```

```
  ++ data is then sent to the viewport manager where it waits to be
  ++ included in a two-dimensional viewport window.
makeGraphImage  :  (L L P,L PAL,L PAL,L PI)                -> $
  ++ makeGraphImage(llp,lpal1,lpal2,lp) returns a graph of the
  ++ domain \spadtype{GraphImage} which is composed of the points
  ++ and lines from the list of lists of points, \spad{llp}, whose
  ++ point colors are indicated by the list of palette colors,
  ++ \spad{lpal1}, and whose lines are colored according to the list
  ++ of palette colors, \spad{lpal2}.  The paramater lp is a list of
  ++ integers which denote the size of the data points.  The graph
  ++ data is then sent to the viewport manager where it waits to be
  ++ included in a two-dimensional viewport window.
makeGraphImage  :  (L L P,L PAL,L PAL,L PI,L DROP)          -> $
  ++ makeGraphImage(llp,lpal1,lpal2,lp,lopt) returns a graph of
  ++ the domain \spadtype{GraphImage} which is composed of the
  ++ points and lines from the list of lists of points, \spad{llp},
  ++ whose point colors are indicated by the list of palette colors,
  ++ \spad{lpal1}, and whose lines are colored according to the list
  ++ of palette colors, \spad{lpal2}.  The paramater lp is a list of
  ++ integers which denote the size of the data points, and \spad{lopt}
  ++ is the list of draw command options.  The graph data is then sent
  ++ to the viewport manager where it waits to be included in a
  ++ two-dimensional viewport window.
pointLists      :  $                                       -> L L P
  ++ pointLists(gi) returns the list of lists of points which compose
  ++ the given graph, \spad{gi}, of the domain \spadtype{GraphImage}.
key             :  $                                       -> I
  ++ key(gi) returns the process ID of the given graph, \spad{gi},
  ++ of the domain \spadtype{GraphImage}.
ranges          :  $                                       -> RANGEF
  ++ ranges(gi) returns the list of ranges of the point components from
  ++ the indicated graph, \spad{gi}, of the domain \spadtype{GraphImage}.
ranges          :  ($,RANGEF)                              -> RANGEF
  ++ ranges(gi,lr) modifies the list of ranges for the given graph,
  ++ \spad{gi} of the domain \spadtype{GraphImage}, to be that of the
  ++ list of range segments, \spad{lr}, and returns the new range list
  ++ for \spad{gi}.
units           :  $                                       -> UNITF
  ++ units(gi) returns the list of unit increments for the x and y
  ++ axes of the indicated graph, \spad{gi}, of the domain
  ++ \spadtype{GraphImage}.
units           :  ($,UNITF)                               -> UNITF
  ++ units(gi,lu) modifies the list of unit increments for the x and y
  ++ axes of the given graph, \spad{gi} of the domain
  ++ \spadtype{GraphImage}, to be that of the list of unit increments,
  ++ \spad{lu}, and returns the new list of units for \spad{gi}.
component       :  ($,L P,PAL,PAL,PI)                      -> Void
  ++ component(gi,lp,pal1,pal2,p) sets the components of the
  ++ graph, \spad{gi} of the domain \spadtype{GraphImage}, to the
  ++ values given.  The point list for \spad{gi} is set to the list
```

```
    ++ \spad{lp}, the color of the points in \spad{lp} is set to
    ++ the palette color \spad{pal1}, the color of the lines which
    ++ connect the points \spad{lp} is set to the palette color
    ++ \spad{pal2}, and the size of the points in \spad{lp} is given
    ++ by the integer p.
  component       :  ($,P)                                  -> Void
    ++ component(gi,pt) modifies the graph \spad{gi} of the domain
    ++ \spadtype{GraphImage} to contain one point component, \spad{pt}
    ++ whose point color, line color and point size are determined by
    ++ the default functions \spadfun{pointColorDefault},
    ++ \spadfun{lineColorDefault}, and \spadfun{pointSizeDefault}.
  component       :  ($,P,PAL,PAL,PI)                       -> Void
    ++ component(gi,pt,pal1,pal2,ps) modifies the graph \spad{gi} of
    ++ the domain \spadtype{GraphImage} to contain one point component,
    ++ \spad{pt} whose point color is set to the palette color \spad{pal1},
    ++ line color is set to the palette color \spad{pal2}, and point
    ++ size is set to the positive integer \spad{ps}.
  appendPoint     :  ($,P)                                  -> Void
    ++ appendPoint(gi,pt) appends the point \spad{pt} to the end
    ++ of the list of points component for the graph, \spad{gi}, which is
    ++ of the domain \spadtype{GraphImage}.
  point           :  ($,P,PAL)                              -> Void
    ++ point(gi,pt,pal) modifies the graph \spad{gi} of the domain
    ++ \spadtype{GraphImage} to contain one point component, \spad{pt}
    ++ whose point color is set to be the palette color \spad{pal}, and
    ++ whose line color and point size are determined by the default
    ++ functions \spadfun{lineColorDefault} and \spadfun{pointSizeDefault}.
  coerce          :  L L P                                  -> $
    ++ coerce(llp)
    ++ component(gi,pt) creates and returns a graph of the domain
    ++ \spadtype{GraphImage} which is composed of the list of list
    ++ of points given by \spad{llp}, and whose point colors, line colors
    ++ and point sizes are determined by the default functions
    ++ \spadfun{pointColorDefault}, \spadfun{lineColorDefault}, and
    ++ \spadfun{pointSizeDefault}.  The graph data is then sent to the
    ++ viewport manager where it waits to be included in a two-dimensional
    ++ viewport window.
  coerce          :  $                                      -> E
    ++ coerce(gi) returns the indicated graph, \spad{gi}, of domain
    ++ \spadtype{GraphImage} as output of the domain \spadtype{OutputForm}.
  putColorInfo    : (L L P,L PAL)                           -> L L P
    ++ putColorInfo(llp,lpal) takes a list of list of points, \spad{llp},
    ++ and returns the points with their hue and shade components
    ++ set according to the list of palette colors, \spad{lpal}.

maxPower: Union(PositiveInteger, "arbitrary") -> %
  ++ maxPower(d) specifies the maximum degree in an algebraic differential
  ++ equation. For example, the degree of (f'')^3 f' is 4. maxPower(-1)
  ++ specifies that the maximum exponent can be arbitrary. This option is
  ++ expressed in the form \spad{maxPower == d}.

homogeneous: Union(PositiveInteger, Boolean) -> %
  ++ homogeneous(d) specifies whether we allow only homogeneous algebraic
  ++ differential equations.  This option is expressed in the form
  ++ \spad{homogeneous == d}.  If true, then maxPower must be
  ++ set, too, and ADEs with constant total degree are allowed.
  ++ If a PositiveInteger is given, only ADE's with this total degree are
  ++ allowed.

Somos: Union(PositiveInteger, Boolean) -> %
  ++ Somos(d) specifies whether we want that the total degree of the
  ++ differential operators is constant, and equal to d, or maxDerivative
  ++ if true. If true, maxDerivative must be set, too.

maxLevel: Union(NonNegativeInteger, "arbitrary") -> %
  ++ maxLevel(d) specifies the maximum number of recursion levels operators
  ++ guessProduct and guessSum will be applied. This option is expressed in
  ++ the form spad{maxLevel == d}.

maxDegree: Union(NonNegativeInteger, "arbitrary") -> %
  ++ maxDegree(d) specifies the maximum degree of the coefficient
  ++ polynomials in an algebraic differential equation or a recursion with
  ++ polynomial coefficients. For rational functions with an exponential
  ++ term, \spad{maxDegree} bounds the degree of the denominator
  ++ polynomial.
  ++ This option is expressed in the form \spad{maxDegree == d}.

maxMixedDegree: NonNegativeInteger -> %
```

```
    ++ maxMixedDegree(d) specifies the maximum q-degree of the coefficient
    ++ polynomials in a recurrence with polynomial coefficients, in the case
    ++ of mixed shifts.  Although slightly inconsistent, maxMixedDegree(0)
    ++ specifies that no mixed shifts are allowed. This option is expressed
    ++ in the form \spad{maxMixedDegree == d}.

  allDegrees: Boolean -> %
    ++ allDegrees(d) specifies whether all possibilities of the degree vector
    ++ - taking into account maxDegree - should be tried. This is mainly
    ++ interesting for rational interpolation. This option is expressed in
    ++ the form \spad{allDegrees == d}.

  safety: NonNegativeInteger -> %
    ++ safety(d) specifies the number of values reserved for testing any
    ++ solutions found. This option is expressed in the form \spad{safety ==
    ++ d}.

  check: Union("skip", "MonteCarlo", "deterministic") -> %
    ++ check(d) specifies how we want to check the solution.  If
    ++ the value is "skip", we return the solutions found by the
    ++ interpolation routine without checking.  If the value is
    ++ "MonteCarlo", we use a probabilistic check.  This option is
    ++ expressed in the form \spad{check == d}

  checkExtraValues: Boolean -> %
    ++ checkExtraValues(d) specifies whether we want to check the
    ++ solution beyond the order given by the degree bounds. This
    ++ option is expressed in the form \spad{checkExtraValues == d}

  one: Boolean -> %
    ++ one(d) specifies whether we are happy with one solution. This option
    ++ is expressed in the form \spad{one == d}.

  debug: Boolean -> %
    ++ debug(d) specifies whether we want additional output on the
    ++ progress. This option is expressed in the form \spad{debug == d}.

  functionName: Symbol -> %
    ++ functionName(d) specifies the name of the function given by the
    ++ algebraic differential equation or recurrence. This option is
    ++ expressed in the form \spad{functionName == d}.

  functionNames: List(Symbol) -> %
    ++ functionNames(d) specifies the names for the function in
    ++ algebraic dependence. This option is
    ++ expressed in the form \spad{functionNames == d}.

  variableName: Symbol -> %
    ++ variableName(d) specifies the variable used in by the algebraic
    ++ differential equation. This option is expressed in the form
```

```
    ++ \spad{variableName == d}.

  indexName: Symbol -> %
    ++ indexName(d) specifies the index variable used for the formulas. This
    ++ option is expressed in the form \spad{indexName == d}.

  displayKind: Symbol -> %
    ++ displayKind(d) specifies kind of the result: generating function,
    ++ recurrence or equation. This option should not be set by the
    ++ user, but rather by the HP-specification.

  option : (List %, Symbol) -> Union(Any, "failed")
    ++ option(l, option) returns which options are given.

++ Author: Martin Rubey
++ Description:
++ GuessOptionFunctions0 provides operations that extract the
++ values of options for Guess.
GuessOptionFunctions0(): Exports == Implementation where

  LGOPT ==> List GuessOption

  Exports == SetCategory with

    maxDerivative: LGOPT -> Union(NonNegativeInteger, "arbitrary")
      ++ maxDerivative returns the specified maxDerivative.

    maxShift: LGOPT -> Union(NonNegativeInteger, "arbitrary")
      ++ maxShift returns the specified maxShift.

    maxSubst: LGOPT -> Union(PositiveInteger, "arbitrary")
      ++ maxSubst returns the specified maxSubst.

    maxPower: LGOPT -> Union(PositiveInteger, "arbitrary")
      ++ maxPower returns the specified maxPower.

    homogeneous: LGOPT -> Union(PositiveInteger, Boolean)
      ++ homogeneous returns whether we allow only homogeneous algebraic
      ++ differential equations, default being false
```

```
Somos: LGOPT -> Union(PositiveInteger, Boolean)
  ++ Somos returns whether we allow only Somos-like operators, default
  ++ being false

maxLevel: LGOPT -> Union(NonNegativeInteger, "arbitrary")
  ++ maxLevel returns the specified maxLevel.

maxDegree: LGOPT -> Union(NonNegativeInteger, "arbitrary")
  ++ maxDegree returns the specified maxDegree.

maxMixedDegree: LGOPT -> NonNegativeInteger
  ++ maxMixedDegree returns the specified maxMixedDegree.

allDegrees: LGOPT -> Boolean
  ++ allDegrees returns whether all possibilities of the degree vector
  ++ should be tried, the default being false.

safety: LGOPT -> NonNegativeInteger
  ++ safety returns the specified safety or 1 as default.

check: LGOPT -> Union("skip", "MonteCarlo", "deterministic")
  ++ check(d) specifies how we want to check the solution.  If
  ++ the value is "skip", we return the solutions found by the
  ++ interpolation routine without checking.  If the value is
  ++ "MonteCarlo", we use a probabilistic check.  The default is
  ++ "deterministic".

checkExtraValues: LGOPT -> Boolean
  ++ checkExtraValues(d) specifies whether we want to check the
  ++ solution beyond the order given by the degree bounds.  The
  ++ default is true.

one: LGOPT -> Boolean
  ++ one returns whether we need only one solution, default being true.

functionName: LGOPT -> Symbol
  ++ functionName returns the name of the function given by the algebraic
  ++ differential equation, default being f

variableName: LGOPT -> Symbol
  ++ variableName returns the name of the variable used in by the
  ++ algebraic differential equation, default being x

indexName: LGOPT -> Symbol
  ++ indexName returns the name of the index variable used for the
  ++ formulas, default being n

displayAsGF: LGOPT -> Boolean
  ++ displayAsGF specifies whether the result is a generating function
```

```
      ++ or a recurrence. This option should not be set by the user, but rather
      ++ by the HP-specification, therefore, there is no default.

    debug: LGOPT -> Boolean
      ++ debug returns whether we want additional output on the progress,
      ++ default being false

    checkOptions: LGOPT -> Void
      ++ checkOptions checks whether the given options are consistent, and
      ++ yields an error otherwise

— Heap.help —

```
=====================================================================
Heap examples
=====================================================================

The domain Heap(S) implements a priority queue of objects of type S
such that the operation extract! removes and returns the maximum
element.  The implementation represents heaps as flexible arrays The
representation and algorithms give complexity of O(log(n)) for
insertion and extractions, and O(n) for construction.
```

```
Create a heap of five elements:

   a:Heap INT:= heap [1,2,3,4,5]
        [5,4,2,1,3]

Use bag to convert a Bag into a Heap:

   bag([1,2,3,4,5])$Heap(INT)
        [5,4,3,1,2]

The operation copy can be used to copy a Heap:

   c:=copy a
        [5,4,2,1,3]

Use empty? to check if the heap is empty:

   empty? a
        false

Use empty to create a new, empty heap:

   b:=empty()$(Heap INT)
        []

and we can see that the newly created heap is empty:

   empty? b
        true

The eq? function compares the reference of one heap to another:

   eq?(a,c)
        false

The extract! function removes largest element of the heap:

   extract! a
        5

Now extract! elements repeatedly until none are left, collecting
the elements in a list.

  [extract!(h) while not empty?(h)]
    [9,7,3,2,- 4,- 7]
                      Type: List Integer

Another way to produce the same result is by defining a heapsort function.

  heapsort(x) == (empty? x => []; cons(extract!(x),heapsort x))
```

```
                    Type: Void

Create another sample heap.

  h1 := heap [17,-4,9,-11,2,7,-7]
    [17,2,9,- 11,- 4,7,- 7]
                    Type: Heap Integer

Apply heapsort to present elements in order.

  heapsort h1
    [17,9,7,2,- 4,- 7,- 11]
                    Type: List Integer

Heaps can be compared with =

   (a=c)@Boolean
        false

and ~=

   (a~=c)
       true

The inspect function shows the largest element in the heap:

   inspect a
       4

The insert! function adds an element to the heap:

   insert!(9,a)
       [9,4,2,1,3]

The map function applies a function to every element of the heap
and returns a new heap:

   map(x+->x+10,a)
       [19,14,12,11,13]

The original heap is unchanged:

   a
       [9,4,2,1,3]

The map! function applies a function to every element of the heap
and returns the original heap with modifications:

   map!(x+->x+10,a)
       [19,14,12,11,13]
```

```
The original heap has been modified:

   a
       [19,14,12,11,13]

The max function returns the largest element in the heap:

   max a
       19

The merge function takes two heaps and creates a new heap with
all of the elements:

   merge(a,c)
       [19,14,12,11,13,5,4,2,1,3]

Notice that the original heap is unchanged:

   a
       [19,14,12,11,13]

The merge! function takes two heaps and modifies the first heap
argument to contain all of the elements:

   merge!(a,c)
       [19,14,12,11,13,5,4,2,1,3]

Notice that the first argument was modified:

   a
       [19,14,12,11,13,5,4,2,1,3]

but the second argument was not:

   c
       [5,4,2,1,3]

A new, empty heap can be created with sample:

   sample()$Heap(INT)
       []

The # function gives the size of the heap:

   #a
       10

The any? function tests each element against a predicate function
and returns true if any pass:
```

```
   any?(x+->(x=14),a)
       true

The every? function tests each element against a predicate function
and returns true if they all pass:

   every?(x+->(x=11),a)
       false

The parts function returns a list of the elements in the heap:

   parts a
       [19,14,12,11,13,5,4,2,1,3]

The size? predicate compares the size of the heap to a value:

   size?(a,9)
       false

The more? predicate asks if the heap size is larger than a value:

   more?(a,9)
       true

The less? predicate asks if the heap size is smaller than a value:

   less?(a,9)
       false

The members function returns a list of the elements of the heap:

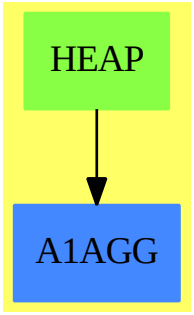
   members a
       [19,14,12,11,13,5,4,2,1,3]

The member? predicate asks if an element is in the heap:

   member?(14,a)
       true

The count function has two forms, one of which counts the number
of copies of an element in the heap:

   count(14,a)
       1



The second form of the count function accepts a predicate to test
against each member of the heap and counts the number of true results:

   count(x+->(x>13),a)
```

```
      2

— HexadecimalExpansion.help —

```
====================================================================
HexadecimalExpansion
====================================================================

All rationals have repeating hexadecimal expansions.  The operation
hex returns these expansions of type HexadecimalExpansion.  Operations
to access the individual numerals of a hexadecimal expansion can be
obtained by converting the value to RadixExpansion(16).  More examples
of expansions are available in the DecimalExpansion, BinaryExpansion,
and RadixExpansion.

This is a hexadecimal expansion of a rational number.

  r := hex(22/7)
      ---
    3.249
                      Type: HexadecimalExpansion

Arithmetic is exact.

  r + hex(6/7)
    4
                      Type: HexadecimalExpansion

The period of the expansion can be short or long ...

  [hex(1/i) for i in 350..354]
       ---------------    ---------      -----    ----------------------
   [0.00BB3EE721A54D88, 0.00BAB6561, 0.00BA2E8, 0.00B9A7862A0FF465879D5F,
       ------------------------------
    0.00B92143FA36F5E02E4850FE8DBD78]
                      Type: List HexadecimalExpansion

or very long!

  hex(1/1007)
     ------------------------------------------------------------------------
   0.0041149783F0BF2C7D13933192AF6980619EE345E91EC2BB9D5CCA5C071E40926E54E8D
     ---------------------------------------------
     DAE24196C0B2F8A0AAD60DBA57F5D4C8536262210C74F1
                      Type: HexadecimalExpansion

These numbers are bona fide algebraic objects.

  p := hex(1/4)*x**2 + hex(2/3)*x + hex(4/9)
        2     _      ---
    0.4x  + 0.Ax + 0.71C
```

```
                    Type: Polynomial HexadecimalExpansion

  q := D(p, x)

                 _
    0.8x + 0.A
                    Type: Polynomial HexadecimalExpansion

  g := gcd(p, q)

          _
    x + 1.5
                    Type: Polynomial HexadecimalExpansion
```

package HTMLFORM HTMLFormat

Here I have put some information about 'how to use' and 'the benefits of' this HTML formatter. Also some information for programmers if they want to extend this package.

If you want information about creating output formatters in general then, rather than duplicating content here I refer you to mathml.spad.pamphlet containing the MathMLFormat domain by Arthur C. Ralfs. This contains useful information for writers of output formatters.

Overview

This package allows users to cut and paste output from the Axiom command line to a HTML page. This output is enabled by typing:

```
)set output html on
```

After this the command line will output html (in addition to other formats that are enabled) and this html code can then be copied and pasted into a HTML document.

The HTML produced is well formed XML, that is, all tags have equivalent closing tags.

Why output to HTML?

In some ways HTMLFormat is a compromise between the standard text output and specialised formats like MathMLFormat. The potential quality is never going to be as good as output to a specialised maths renderer but on the other hand it is a lot better than the clunky fixed width font text output. The quality is not the only issue though, the direct output in any format is unlikely to be exactly what the user wants, so possibly more important than quality is the ability to edit the output.

HTMLFormat has advantages that the other output formats don't, for instance,

- It works with any browser without the need for plugins (as far as I know most computers should have the required fonts)
- Users can easily annotate and add comments using colour, bold, underline and so on.
- Annotations can easily be done with whatever html editor or text editor you are familiar with.
- Edits to the output will cause the width of columns and so on to be automatically adjusted, no need to try to insert spaces to get the superscripts to line up again!
- It is very easy to customise output so, for instance, we can fit a lot of information in a compact space on the page.

Using the formatter

We can cause the command line interpreter to output in html by typing the following:

```
)set output html on
```

After this the command line will output html (in addition to other formats that are enabled) and this html code can then be copied and pasted into an existing HTML document.

If you do not already have an html page to copy the output to then you can create one with a text editor and entering the following:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"
 "http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" >
```

```
 <head>
  <title>Enter Your Title Here</title>
 </head>
 <body>
  Copy and paste the output from command line here.
 </body>
</html>
```

Or using any program that will export to html such as OpenOffice.org writer.

Form of the output

```
HTMLFormat does not try to interpret syntax, for instance in an example like:
(1) -> integral(x^x,x)
it just takes what OutputForm provides and does not try to replace
%A with the bound variable x.
```

Matrix Formatting

A big requirement for me is to fit big matrices on ordinary web pages.

At the moment the default output for a matrix is a grid, however it easy to modify this for a single matrix, or a whole page or whole site by using css (cascading style sheets). For instance we can get a more conventional looking matrix by adding the following style to the top of the page after the ¡head¿ tag:

```
<style type="text/css">
#matl {border-left-style:solid}
#matr {border-right-style:solid}
#matlt {border-left-style:solid;border-top-style:solid}
#matrt {border-right-style:solid;border-top-style:solid}
#matlb {border-left-style:solid;border-bottom-style:solid}
#matrb {border-right-style:solid;border-bottom-style:solid}
</style>
```

There are many other possibilities, for instance we can generate a matrix with bars either side to indicate a determinant. All we have to do is change the css for the site, page or individual element.

Programmers Guide

This package converts from OutputForm, which is a hierarchical tree structure, to html which uses tags arranged in a hierarchical tree structure. So the package converts from one tree (graph) structure to another.

This conversion is done in two stages using an intermediate Tree String structure. This Tree String structure represents HTML where:

- leafs represents unstructured text
- string in leafs contains the text
- non-leafs represents xml elements
- string in non-leafs represents xml attributes

This is created by traversing OutputForm while building up the Tree String structure.

The second stage is to convert the Tree Structure to text. All text output is done using:

```
sayTeX$Lisp
```

I have not produced and output to String as I don't know a way to append to a long string efficiently and I don't know how to insert carriage- returns into a String.

Future Developments

There would be some benefits in creating a XMLFormat category which would contain common elements for all xml formatted outputs such as HTMLFormat, MathMLFormat, SVGFormat and X3DFormat. However programming effort might be better spent creating a version of OutputForm which has better syntax information.

)abbrev domain HTMLFORM HTMLFormat
++ Author: Martin J Baker, Arthur C. Ralfs, Robert S. Sutor
++ Date: January 2010
++ Description:
++ HtmlFormat provides a coercion from OutputForm to html.
HTMLFormat(): public == private where
  E      ==> OutputForm
  I      ==> Integer
  L      ==> List
  S      ==> String

  public == SetCategory with
    coerce:    E -> S
      ++ coerce(o) changes o in the standard output format to html format.
      ++
      ++X coerce(sqrt(3+x)::OutputForm)$HTMLFORM
    coerceS:   E -> S
      ++ coerceS(o) changes o in the standard output format to html
      ++ format and displays formatted result.
      ++
      ++X coerceS(sqrt(3+x)::OutputForm)$HTMLFORM
    coerceL:   E -> S
      ++ coerceL(o) changes o in the standard output format to html
      ++ format and displays result as one long string.
      ++
      ++X coerceL(sqrt(3+x)::OutputForm)$HTMLFORM
    exprex:    E -> S
```

```
    ++ exprex(o) coverts \spadtype{OutputForm} to \spadtype{String}
    ++
    ++X exprex(sqrt(3+x)::OutputForm)$HTMLFORM
  display:   S -> Void
    ++ display(o) prints the string returned by coerce.
    ++
    ++X display(coerce(sqrt(3+x)::OutputForm)$HTMLFORM)$HTMLFORM

====================================================================
MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
====================================================================

DistributedMultivariatePolynomial which is abbreviated as DMP and
HomogeneousDistributedMultivariatePolynomial, which is abbreviated
as HDMP, are very similar to MultivariatePolynomial except that
they are represented and displayed in a non-recursive manner.

  (d1,d2,d3) : DMP([z,y,x],FRAC INT)
                      Type: Void

The constructor DMP orders its monomials lexicographically while
HDMP orders them by total order refined by reverse lexicographic
```

```
order.

  d1 := -4*z + 4*y**2*x + 16*x**2 + 1
            2       2
   - 4z + 4y x + 16x  + 1
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

  d2 := 2*z*y**2 + 4*x + 1
       2
   2z y  + 4x + 1
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

  d3 := 2*z*x**2 - 2*y**2 - x
       2     2
   2z x  - 2y  - x
            Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

These constructors are mostly used in Groebner basis calculations.

  groebner [d1,d2,d3]
        1568  6   1264  5    6   4   182  3   2047  2    103      2857

                                                    Fraction Integer)
```

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term ordering.

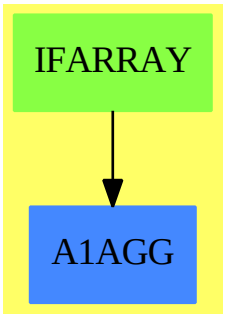
— IndexedFlexibleArray.help —

```
=====================================================================
IndexedFlexibleArray examples
=====================================================================

A FlexibleArray is the notion of an array intended to allow for growth
at the end only.  Hence the following efficient operations
  append(x,a)  meaning append item x at the end of the array a
  delete(a,n)} meaning delete the last item from the array a



Flexible arrays support the other operations inherited from
ExtensibleLinearAggregate. However, these are not efficient.

Flexible arrays combine the O(1) access time property of arrays
with growing and shrinking at the end in O(1) (average) time.
This is done by using an ordinary array which may have zero or more
empty slots at the end.  When the array becomes full it is copied
into a new larger (50% larger) array.  Conversely, when the array
becomes less than 1/2 full, it is copied into a smaller array.
Flexible arrays provide for an efficient implementation of many
data structures in particular heaps, stacks and sets.

++ \spad{delete(a,n)} meaning delete the last item from the array \spad{a}\br
++ Flexible arrays support the other operations inherited from
++ \spadtype{ExtensibleLinearAggregate}. However, these are not efficient.
++ Flexible arrays combine the \spad{O(1)} access time property of arrays
++ with growing and shrinking at the end in \spad{O(1)} (average) time.
++ This is done by using an ordinary array which may have zero or more
++ empty slots at the end.  When the array becomes full it is copied
++ into a new larger (50% larger) array.  Conversely, when the array
++ becomes less than 1/2 full, it is copied into a smaller array.
++ Flexible arrays provide for an efficient implementation of many
++ data structures in particular heaps, stacks and sets.

=====================================================================
IndexedList examples
=====================================================================

IndexedList is a basic implementation of the functions in
ListAggregate, often using functions in the underlying LISP
system. The second parameter to the constructor (mn) is the beginning
index of the list. That is, if l is a list, then elt(l,mn) is the
first value. This constructor is probably best viewed as the
implementation of singly-linked lists that are addressable by index
rather than as a mere wrapper for LISP lists.

IndexedMatrix examples
=====================================================================
```

```
An IndexedMatrix is a matrix where the minimal row and column
indices are parameters of the type.  The domains Row and Col
are both IndexedVectors.

The index of the 'first' row may be obtained by calling the function
minRowIndex. The index of the 'first' column may be obtained by calling
the function minColIndex.  The index of the first element of a 'Row' is
the same as the index of the first column in a matrix and vice versa.

domain IARRAY2 IndexedTwoDimensionalArray

An IndexedTwoDimensionalArray is a 2-dimensional array where the minimal row and column indices are parameters of the type. Rows and columns are returned as IndexedOneDimensionalArray's with minimal indices matching those of the IndexedTwoDimensionalArray. The index of the 'first' row may be obtained by calling the function 'minRowIndex'. The index of the 'first' column may be obtained by calling the function 'minColIndex'. The index of the first element of a 'Row' is the same as the index of the first column in an array and vice versa.
