```
)abbrev domain ITAYLOR InnerTaylorSeries
++ Author: Clifton J. Williamson
```

```
++ Date Created: 21 December 1989
++ Date Last Updated: 25 February 1989
++ Description:
++ Internal package for dense Taylor series.
++ This is an internal Taylor series type in which Taylor series
++ are represented by a \spadtype{Stream} of \spadtype{Ring} elements.
++ For univariate series, the \spad{Stream} elements are the Taylor
++ coefficients. For multivariate series, the \spad{n}th Stream element
++ is a form of degree n in the power series variables.

InnerTaylorSeries(Coef): Exports == Implementation where
  Coef  : Ring
  I   ==> Integer
  NNI ==> NonNegativeInteger
  ST  ==> Stream Coef
  STT ==> StreamTaylorSeriesOperations Coef

  Exports ==> Ring with
    coefficients: % -> Stream Coef
      ++\spad{coefficients(x)} returns a stream of ring elements.
      ++ When x is a univariate series, this is a stream of Taylor
      ++ coefficients. When x is a multivariate series, the
      ++ \spad{n}th element of the stream is a form of
      ++ degree n in the power series variables.
    series: Stream Coef -> %
      ++\spad{series(s)} creates a power series from a stream of
      ++ ring elements.
      ++ For univariate series types, the stream s should be a stream
      ++ of Taylor coefficients. For multivariate series types, the
      ++ stream s should be a stream of forms the \spad{n}th element
      ++ of which is a
      ++ form of degree n in the power series variables.
    pole?: % -> Boolean
      ++\spad{pole?(x)} tests if the series x has a pole.
      ++ Note: this is false when x is a Taylor series.
    order: % -> NNI
      ++\spad{order(x)} returns the order of a power series x,
      ++ i.e. the degree of the first non-zero term of the series.
    order: (%,NNI) -> NNI
      ++\spad{order(x,n)} returns the minimum of n and the order of x.
    "*" : (Coef,%)->%
      ++\spad{c*x} returns the product of c and the series x.
    "*" : (%,Coef)->%
      ++\spad{x*c} returns the product of c and the series x.
    "*" : (%,Integer)->%
      ++\spad{x*i} returns the product of integer i and the series x.
    if Coef has IntegralDomain then IntegralDomain

      ++ all the nested operations flattened to triples using new
      ++ local variables.
      ++ If s is a piece of code, this speeds up
      ++ the compilation tremendously later on.
    unparse  : % -> String
      ++ unparse(f) returns a string s such that the parser
      ++ would transform s to f.
      ++ Error: if f is not the parsed form of a string.
    parse : String -> %
      ++ parse(s) is the inverse of unparse. It parses a string to InputForm.
    declare  : List %   -> Symbol
```

```
      ++ declare(t) returns a name f such that f has been
      ++ declared to the interpreter to be of type t, but has
      ++ not been assigned a value yet.
      ++ Note: t should be created as \spad{devaluate(T)$Lisp} where T is the
      ++ actual type of f (this hack is required for the case where
      ++ T is a mapping type).
    compile  : (Symbol, List %) -> Symbol
      ++ \spad{compile(f, [t1,...,tn])} forces the interpreter to compile
      ++ the function f with signature \spad{(t1,...,tn) -> ?}.
      ++ returns the symbol f if successful.
      ++ Error: if f was not defined beforehand in the interpreter,
      ++ or if the ti's are not valid types, or if the compiler fails.

=====================================================================
Integer examples
=====================================================================

Axiom provides many operations for manipulating arbitrary precision
integers.  In this section we will show some of those that come from
Integer itself plus some that are implemented in other packages.

\subsection{Basic Functions}

The size of an integer in Axiom is only limited by the amount of
computer storage you have available.  The usual arithmetic operations
are available.

  2**(5678 - 4856 + 2 * 17)
  48048107704350081471815409251259243912395261398716822634738556100880842000076_
   30829308634252709141208374307457227821149607627692202643343568752733498024 9_
   53930242542523045817764949544214392905306388478705146745768073877141698859 8_
   15495632935288783334250628775936
                        Type: PositiveInteger

There are a number of ways of working with the sign of an integer.
Let's use this x as an example.

  x := -101
    - 101
                        Type: Integer

First of all, there is the absolute value function.

  abs(x)
    101
                        Type: PositiveInteger

The sign operation returns -1 if its argument is negative, 0 if zero
and 1 if positive.

  sign(x)
    - 1
                        Type: Integer

You can determine if an integer is negative in several other ways.
```

```
  x < 0
    true
                          Type: Boolean

  x <= -1
    true
                          Type: Boolean

  negative?(x)
    true
                          Type: Boolean
```

Similarly, you can find out if it is positive.

```
  x > 0
    false
                          Type: Boolean

  x >= 1
    false
                          Type: Boolean

  positive?(x)
    false
                          Type: Boolean
```

This is the recommended way of determining whether an integer is zero.

```
  zero?(x)
    false
                          Type: Boolean
```

Use the zero? operation whenever you are testing any mathematical object for equality with zero. This is usually more efficient that using = (think of matrices: it is easier to tell if a matrix is zero by just checking term by term than constructing another "zero" matrix and comparing the two matrices term by term) and also avoids the problem that = is usually used for creating equations.

This is the recommended way of determining whether an integer is equal to one.

```
  one?(x)
    false
                         Type: Boolean
```

This syntax is used to test equality using =. It says that you want a Boolean (true or false) answer rather than an equation.

```
  (x = -101)@Boolean
```

```
    true
                        Type: Boolean
```

The operations odd? and even? determine whether an integer is odd or even, respectively. They each return a Boolean object.

```
  odd?(x)
    true
                        Type: Boolean

  even?(x)
    false
                        Type: Boolean
```

The operation gcd computes the greatest common divisor of two integers.

```
  gcd(56788,43688)
    4
                        Type: PositiveInteger
```

The operation lcm computes their least common multiple.

```
  lcm(56788,43688)
    620238536
                        Type: PositiveInteger
```

To determine the maximum of two integers, use max.

```
  max(678,567)
    678
                        Type: PositiveInteger
```

To determine the minimum, use min.

```
  min(678,567)
    567
                        Type: PositiveInteger
```

The reduce operation is used to extend binary operations to more than two arguments. For example, you can use reduce to find the maximum integer in a list or compute the least common multiple of all integers in the list.

```
  reduce(max,[2,45,-89,78,100,-45])
    100
                        Type: PositiveInteger

  reduce(min,[2,45,-89,78,100,-45])
    - 89
                        Type: Integer
```

```
  reduce(gcd,[2,45,-89,78,100,-45])
    1
                        Type: PositiveInteger

  reduce(lcm,[2,45,-89,78,100,-45])
    1041300
                        Type: PositiveInteger
```

The infix operator "/" is not used to compute the quotient of integers.
Rather, it is used to create rational numbers as described in Fraction.

```
  13 / 4
     13
     --
      4
                        Type: Fraction Integer
```

The infix operation quo computes the integer quotient.

```
  13 quo 4
    3
                        Type: PositiveInteger
```

The infix operation rem computes the integer remainder.

```
  13 rem 4
    1
                        Type: PositiveInteger
```

One integer is evenly divisible by another if the remainder is zero.
The operation exquo can also be used.

```
  zero?(167604736446952 rem 2003644)
    true
                        Type: Boolean
```

The operation divide returns a record of the quotient and remainder
and thus is more efficient when both are needed.

```
  d := divide(13,4)
    [quotient= 3,remainder= 1]
                        Type: Record(quotient: Integer,remainder: Integer)

  d.quotient
    3
                        Type: PositiveInteger
```

See help on Records for details on Records.

```
  d.remainder
    1
                        Type: PositiveInteger

========================================================================
Primes and Factorization
========================================================================

Use the operation factor to factor integers.  It returns an object of
type Factored Integer.

  factor 102400
     12 2
    2  5
                        Type: Factored Integer

The operation prime? returns true or false depending on whether its
argument is a prime.

  prime? 7
    true
                        Type: Boolean

  prime? 8
    false
                        Type: Boolean

The operation nextPrime returns the least prime number greater than
its argument.

  nextPrime 100
    101
                        Type: PositiveInteger

The operation prevPrime returns the greatest prime number less than
its argument.

  prevPrime 100
    97
                        Type: PositiveInteger

To compute all primes between two integers (inclusively), use the
operation primes.

  primes(100,175)
    [173,167,163,157,151,149,139,137,131,127,113,109,107,103,101]
                        Type: List Integer

You might sometimes want to see the factorization of an integer
when it is considered a Gaussian integer.
```

```
  factor(2 :: Complex Integer)
                  2
    - %i (1 + %i)
                       Type: Factored Complex Integer
```

```
=====================================================================
Some Number Theoretic Functions
=====================================================================
```

Axiom provides several number theoretic operations for integers.

The operation fibonacci computes the Fibonacci numbers. The algorithm has running time O(log^3n) for argument n.

```
  [fibonacci(k) for k in 0..]
    [0,1,1,2,3,5,8,13,21,34,...]
                       Type: Stream Integer
```

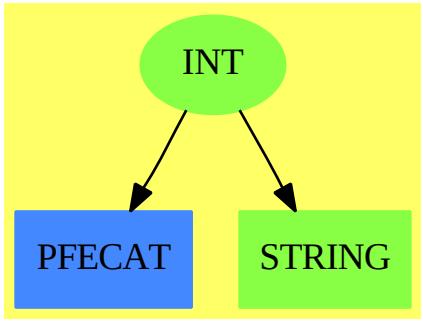
The operation legendre computes the Legendre symbol for its two integer arguments where the second one is prime. If you know the second argument to be prime, use jacobi instead where no check is made.

```
  [legendre(i,11) for i in 0..10]
    [0,1,- 1,1,1,1,- 1,- 1,- 1,1,- 1]
                       Type: List Integer
```

The operation jacobi computes the Jacobi symbol for its two integer arguments. By convention, 0 is returned if the greatest common divisor of the numerator and denominator is not 1.

```
  [jacobi(i,15) for i in 0..9]
    [0,1,1,0,1,0,0,- 1,1,0]
                       Type: List Integer
```

The operation eulerPhi computes the values of Euler's \phi-function where \phi(n) equals the number of positive integers less than or equal to n that are relatively prime to the positive integer n.



```
  [eulerPhi i for i in 1..]
    [1,1,2,2,4,2,6,4,6,4,...]
                       Type: Stream Integer
```

The operation moebiusMu computes the Moebius mu function.

```
  [moebiusMu i for i in 1..]
    [1,- 1,- 1,0,- 1,1,- 1,0,0,1,...]
                       Type: Stream Integer
```

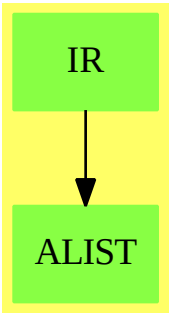
IntegrationResult examples
=====================================================================

The result of a transcendental integration.



If a function f has an elementary integral g, then g can be written
in the form
    g = h + c1 log(u1) + c2 log(u2) + ... + cn log(un)
where h, which is in the same field than f, is called the rational
part of the integral, and
    c1 log(u1) + ... cn log(un)
is called the logarithmic part of the integral. This domain manipulates
integrals represented in that form, by keeping both parts separately.
The logs are not explicitly computed.

====================================================================
Kernel examples
====================================================================

A kernel is a symbolic function application (such as sin(x+ y))
or a symbol (such as x).  More precisely, a non-symbol
kernel over a set S is an operator applied to a given list of
arguments from S.  The operator has type BasicOperator
and the kernel object is usually part of an Expression object.

Kernels are created implicitly for you when you create expressions.
```

```
  x :: Expression Integer
    x
                          Type: Expression Integer
```

You can directly create a "symbol" kernel by using the kernel operation.

```
  kernel x
    x
                          Type: Kernel Expression Integer
```

This expression has two different kernels.

```
  sin(x) + cos(x)
    sin(x) + cos(x)
                          Type: Expression Integer
```

The operator kernels returns a list of the kernels in an object of type Expression.

```
  kernels %
    [sin(x),cos(x)]
                          Type: List Kernel Expression Integer
```

This expression also has two different kernels.

```
  sin(x)**2 + sin(x) + cos(x)
          2
    sin(x)  + sin(x) + cos(x)
                          Type: Expression Integer
```

The sin(x) kernel is used twice.

```
  kernels %
    [sin(x),cos(x)]
                          Type: List Kernel Expression Integer
```

An expression need not contain any kernels.

```
  kernels(1 :: Expression Integer)
    []
                          Type: List Kernel Expression Integer
```

If one or more kernels are present, one of them is designated the main kernel.

```
  mainKernel(cos(x) + tan(x))
    tan(x)
                          Type: Union(Kernel Expression Integer,...)
```

```
Kernels can be nested. Use height  to determine the nesting depth.

  height kernel x
    1
                          Type: PositiveInteger

This has height 2 because the x has height 1 and then we apply an
operator to that.

  height mainKernel(sin x)
    2
                          Type: PositiveInteger

  height mainKernel(sin cos x)
    3
                          Type: PositiveInteger

  height mainKernel(sin cos (tan x + sin x))
    4
                          Type: PositiveInteger

Use the operator operation to extract the operator component of the
kernel.  The operator has type BasicOperator.

  operator mainKernel(sin cos (tan x + sin x))
    sin
                          Type: BasicOperator

Use the name operation to extract the name of the operator component
of the kernel.  The name has type Symbol.  This is really just a
shortcut for a two-step process of extracting the operator and then
calling name on the operator.

  name mainKernel(sin cos (tan x + sin x))
    sin
                          Type: Symbol

Axiom knows about functions such as sin, cos and so on and can make
kernels and then expressions using them.  To create a kernel and
expression using an arbitrary operator, use operator.

Now f can be used to create symbolic function applications.

  f := operator 'f
    f
                         Type: BasicOperator

  e := f(x, y, 10)
    f(x,y,10)
                         Type: Expression Integer
```

```
Use the is? operation to learn if the operator component of a kernel
is equal to a given operator.

  is?(e, f)
    true
                        Type: Boolean

You can also use a symbol or a string as the second argument to is?.

  is?(e, 'f)
    true
                        Type: Boolean

Use the argument operation to get a list containing the argument
component of a kernel.

  argument mainKernel e
    [x,y,10]
                        Type: List Expression Integer

Conceptually, an object of type Expression can be thought of a
quotient of multivariate polynomials, where the "variables" are
kernels.  The arguments of the kernels are again expressions and so
the structure recurses.  See Expression for examples of using kernels
to take apart expression objects.

)abbrev domain KERNEL Kernel
++ Author: Manuel Bronstein
++ Date Created: 22 March 1988
++ Date Last Updated: 10 August 1994
++ Description:
++ A kernel over a set S is an operator applied to a given list
++ of arguments from S.

Kernel(S:OrderedSet): Exports == Implementation where
  O  ==> OutputForm
  N  ==> NonNegativeInteger
  OP ==> BasicOperator

  SYMBOL  ==> "%symbol"
  PMPRED  ==> "%pmpredicate"
  PMOPT   ==> "%pmoptional"
  PMMULT  ==> "%pmmultiple"
  PMCONST ==> "%pmconstant"
  SPECIALDISP  ==> "%specialDisp"
  SPECIALEQUAL ==> "%specialEqual"
  SPECIALINPUT ==> "%specialInput"

  Exports ==> Join(CachableSet, Patternable S) with
    name    : % -> Symbol
```

```
    ++ name(op(a1,...,an)) returns the name of op.
  operator: % -> OP
    ++ operator(op(a1,...,an)) returns the operator op.
  argument: % -> List S
    ++ argument(op(a1,...,an)) returns \spad{[a1,...,an]}.
  height  : % -> N
    ++ height(k) returns the nesting level of k.
  kernel  : (OP, List S, N) -> %
    ++ kernel(op, [a1,...,an], m) returns the kernel \spad{op(a1,...,an)}
    ++ of nesting level m.
    ++ Error: if op is k-ary for some k not equal to m.
  kernel  : Symbol -> %
    ++ kernel(x) returns x viewed as a kernel.
  symbolIfCan: % -> Union(Symbol, "failed")
    ++ symbolIfCan(k) returns k viewed as a symbol if k is a symbol, and
    ++ "failed" otherwise.
  is?     : (%, OP) -> Boolean
    ++ is?(op(a1,...,an), f) tests if op = f.
  is?     : (%, Symbol) -> Boolean
    ++ is?(op(a1,...,an), s) tests if the name of op is s.
  if S has ConvertibleTo InputForm then ConvertibleTo InputForm

— KeyedAccessFile.help —

```
====================================================================
KeyedAccessFile examples
====================================================================

The domain KeyedAccessFile(S) provides files which can be used
as associative tables.  Data values are stored in these files and can
be retrieved according to their keys.  The keys must be strings so
this type behaves very much like the StringTable(S) domain.  The
difference is that keyed access files reside in secondary storage
while string tables are kept in memory.

Before a keyed access file can be used, it must first be opened.
A new file can be created by opening it for output.

  ey: KeyedAccessFile(Integer) := open("editor.year", "output")

Just as for vectors, tables or lists, values are saved in a keyed
access file by setting elements.

  ey."Char":= 1986

  ey."Caviness" := 1985

  ey."Fitch"    := 1984

Values are retrieved using application, in any of its syntactic forms.

  ey."Char"

  ey("Char")

  ey "Char"

Attempting to retrieve a non-existent element in this way causes an
error.  If it is not known whether a key exists, you should use the
```

```
search operation.

  search("Char", ey)

  search("Smith", ey)

When an entry is no longer needed, it can be removed from the file.

  remove!("Char", ey)

The keys operation returns a list of all the keys for a given file.

  keys ey

The # operation gives the number of entries.

  #ey

The table view of keyed access files provides safe operations.  That
is, if the Axiom program is terminated between file operations, the
file is left in a consistent, current state.  This means, however,
that the operations are somewhat costly.  For example, after each
update the file is closed.

Here we add several more items to the file, then check its contents.

  KE := Record(key: String, entry: Integer)

  reopen!(ey, "output")

If many items are to be added to a file at the same time, then it is
more efficient to use the write operation.

  write!(ey, ["van Hulzen", 1983]$KE)

  write!(ey, ["Calmet", 1982]$KE)

  write!(ey, ["Wang", 1981]$KE)

  close! ey

The read operation is also available from the file view, but it
returns elements in a random order.  It is generally clearer and more
efficient to use the keys operation and to extract elements by key.

  keys ey

  members ey

— domain KAFILE KeyedAccessFile —

```
)abbrev domain KAFILE KeyedAccessFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain allows a random access file to be viewed both as a table
++ and as a file object. The KeyedAccessFile format is a directory
++ containing a single file called ‘‘index.kaf’’. This file is a random
++ access file. The first thing in the file is an integer which is the
++ byte offset of an association list (the dictionary) at the end of
++ the file. The association list is of the form
++ ((key . byteoffset) (key . byteoffset)...)
++ where the byte offset is the number of bytes from the beginning of
++ the file. This offset contains an s-expression for the value of the key.

KeyedAccessFile(Entry): KAFcategory == KAFcapsule where
    Name  ==> FileName
    Key   ==> String
    Entry :   SetCategory

    KAFcategory ==
        Join(FileCategory(Name, Record(key: Key, entry: Entry)),
             TableAggregate(Key, Entry)) with
                 finiteAggregate
                 pack_!: % -> %
                     ++ pack!(f) reorganizes the file f on disk to recover
                     ++ unused space.

    KAFcapsule == add

        CLASS     ==> 131   -- an arbitrary no. greater than 127
```

=====================================================================
Library examples
=====================================================================

The Library domain provides a simple way to store Axiom values
in a file.  This domain is similar to KeyedAccessFile but fewer
declarations are needed and items of different types can be saved
together in the same file.

To create a library, you supply a file name.

  stuff := library "Neat.stuff"

Now values can be saved by key in the file.  The keys should be
mnemonic, just as the field names are for records.  They can be given
either as strings or symbols.

  stuff.int := 32**2

  stuff."poly" := x**2 + 1

  stuff.str := "Hello"

You obtain the set of available keys using the keys operation.
```

```
  keys stuff

You extract values by giving the desired key in this way.

  stuff.poly

  stuff("poly")

When the file is no longer needed, you should remove it from the
file system.

  )system rm -rf Neat.stuff

```
)abbrev domain LIB Library
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides a simple way to save values in files.

Library(): TableAggregate(String, Any) with
         library:  FileName -> %
             ++ library(ln) creates a new library file.
         pack_!: % -> %
             ++ pack!(f) reorganizes the file f on disk to recover
             ++ unused space.

         elt : (%, Symbol) -> Any
             ++ elt(lib,k) or lib.k  extracts the value corresponding to
             ++ the key \spad{k} from the library \spad{lib}.

         setelt : (%, Symbol, Any) -> Any
             ++ \spad{lib.k := v} saves the value \spad{v} in the library
             ++ \spad{lib}.  It can later be extracted using the key \spad{k}.

         close_!: % -> %
          ++ close!(f) returns the library f closed to input and output.

    == KeyedAccessFile(Any) add
         Rep := KeyedAccessFile(Any)
         library f == open f
         elt(f:%,v:Symbol) == elt(f, string v)
         setelt(f:%, v:Symbol, val:Any) == setelt(f, string v, val)

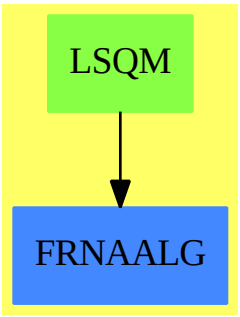
LieSquareMatrix examples
=====================================================================



LieSquareMatrix(n,R) implements the Lie algebra of the n by n
matrices over the commutative ring R.

The Lie bracket (commutator) of the algebra is given by
   a*b := (a *$SQMATRIX(n,R) b - b *$SQMATRIX(n,R) a)
where *$SQMATRIX(n,R) is the usual matrix multiplication.

```
=====================================================================
LinearOrdinaryDifferentialOperator examples
=====================================================================

LinearOrdinaryDifferentialOperator(A, diff) is the domain of linear
ordinary differential operators with coefficients in a ring A with a
given derivation.
```

```
=====================================================================
Differential Operators with Series Coefficients
=====================================================================

Problem:
  Find the first few coefficients of exp(x)/x^i of Dop phi where

    Dop := D^3 + G/x^2 * D + H/x^3 - 1
    phi := sum(s[i]*exp(x)/x^i, i = 0..)

Solution:

Define the differential.

  Dx: LODO(EXPR INT, f +-> D(f, x))
                          Type: Void

  Dx := D()
   D
     Type: LinearOrdinaryDifferentialOperator(Expression Integer,
      theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,
              SPADCALL(G1404,QUOTE x,
               ELT(*1;anonymousFunction;0;frame0;internal;MV,0))))

Now define the differential operator Dop.

  Dop:= Dx^3 + G/x^2*Dx + H/x^3 - 1
                        3
     3    G     - x  + H
    D  + -- D + --------
          2         3
         x         x
     Type: LinearOrdinaryDifferentialOperator(Expression Integer,
      theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,
              SPADCALL(G1404,QUOTE x,
               ELT(*1;anonymousFunction;0;frame0;internal;MV,0))))

  n == 3
                          Type: Void

  phi == reduce(+,[subscript(s,[i])*exp(x)/x^i for i in 0..n])
                          Type: Void

  phi1 ==  Dop(phi) / exp x
                          Type: Void

  phi2 == phi1 *x**(n+3)
                          Type: Void
```

```
  phi3 == retract(phi2)@(POLY INT)
                          Type: Void

  pans == phi3 ::UP(x,POLY INT)
                          Type: Void

  pans1 == [coefficient(pans, (n+3-i) :: NNI) for i in 2..n+1]
                          Type: Void

  leq == solve(pans1,[subscript(s,[i]) for i in 1..n])
                          Type: Void
```

Evaluate this for several values of n.

```

====================================================================
LinearOrdinaryDifferentialOperator1 example
====================================================================

LinearOrdinaryDifferentialOperator1(A) is the domain of linear
ordinary differential operators with coefficients in the differential
ring A.
```

```
=====================================================================
Differential Operators with Rational Function Coefficients
=====================================================================

This example shows differential operators with rational function
coefficients.  In this case operator multiplication is non-commutative and,
since the coefficients form a field, an operator division algorithm exists.

We begin by defining RFZ to be the rational functions in x with
integer coefficients and Dx to be the differential operator for d/dx.

  RFZ := Fraction UnivariatePolynomial('x, Integer)
    Fraction UnivariatePolynomial(x,Integer)
                          Type: Domain

  x : RFZ := 'x
    x
                          Type: Fraction UnivariatePolynomial(x,Integer)

  Dx : LODO1 RFZ := D()
    D
                          Type: LinearOrdinaryDifferentialOperator1
                                  Fraction UnivariatePolynomial(x,Integer)

Operators are created using the usual arithmetic operations.

  b : LODO1 RFZ := 3*x**2*Dx**2 + 2*Dx + 1/x
      2 2         1
    3x D  + 2D + -
                x
                          Type: LinearOrdinaryDifferentialOperator1
                                 Fraction UnivariatePolynomial(x,Integer)

  a : LODO1 RFZ := b*(5*x*Dx + 7)
       3 3       2        2         7
    15x D  + (51x  + 10x)D  + 29D + -
                                    x
                         Type: LinearOrdinaryDifferentialOperator1
                                 Fraction UnivariatePolynomial(x,Integer)

Operator multiplication corresponds to functional composition.

  p := x**2 + 1/x**2
     4
    x  + 1
    ------
       2
      x
                         Type: Fraction UnivariatePolynomial(x,Integer)
```

```
Since operator coefficients depend on x, the multiplication is not
commutative.

  (a*b - b*a) p
         4
    - 75x  + 540x - 75
    ------------------
             4
            x
                        Type: Fraction UnivariatePolynomial(x,Integer)

When the coefficients of operator polynomials come from a field, as in
this case, it is possible to define operator division.  Division on
the left and division on the right yield different results when the
multiplication is non-commutative.

The results of leftDivide and rightDivide are quotient-remainder pairs
satisfying:

  leftDivide(a,b) = [q, r] such that  a = b*q + r
  rightDivide(a,b) = [q, r] such that a = q*b + r

In both cases, the degree of the remainder, r, is less than the degree
of b.

  ld := leftDivide(a,b)
    [quotient= 5x D + 7,remainder= 0]
      Type: Record(quotient: LinearOrdinaryDifferentialOperator1
                               Fraction UnivariatePolynomial(x,Integer),
                   remainder: LinearOrdinaryDifferentialOperator1
                               Fraction UnivariatePolynomial(x,Integer))

  a = b * ld.quotient + ld.remainder
       3 3       2        2         7     3 3       2        2         7
    15x D  + (51x  + 10x)D  + 29D + -= 15x D  + (51x  + 10x)D  + 29D + -
      Type: Equation LinearOrdinaryDifferentialOperator1
                       Fraction UnivariatePolynomial(x,Integer)

The operations of left and right division are so-called because the
quotient is obtained by dividing a on that side by b.

  rd := rightDivide(a,b)
    [quotient= 5x D + 7,remainder= 10D + -]
      Type: Record(quotient: LinearOrdinaryDifferentialOperator1
                               Fraction UnivariatePolynomial(x,Integer),
                   remainder: LinearOrdinaryDifferentialOperator1
                               Fraction UnivariatePolynomial(x,Integer))

  a = rd.quotient * b + rd.remainder
       3 3       2        2         7     3 3       2        2         7
```

```
    15x D  + (51x  + 10x)D  + 29D + -= 15x D  + (51x  + 10x)D  + 29D + -
     Type: Equation LinearOrdinaryDifferentialOperator1
                     Fraction UnivariatePolynomial(x,Integer)
```

Operations rightQuotient and rightRemainder are available if only one of the quotient or remainder are of interest to you. This is the quotient from right division.

```
  rightQuotient(a,b)
    5x D + 7
     Type: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer)
```

This is the remainder from right division. The corresponding "left" functions, leftQuotient and leftRemainder are also available.

```
  rightRemainder(a,b)
          5
    10D + -
          x
      Type: LinearOrdinaryDifferentialOperator1
              Fraction UnivariatePolynomial(x,Integer)
```

For exact division, operations leftExactQuotient and rightExactQuotient are supplied. These return the quotient but only if the remainder is zero. The call rightExactQuotient(a,b) would yield an error.

```
  leftExactQuotient(a,b)
    5x D + 7
     Type: Union(LinearOrdinaryDifferentialOperator1
                   Fraction UnivariatePolynomial(x,Integer),...)
```

The division operations allow the computation of left and right greatest common divisors, leftGcd and rightGcd via remainder sequences, and consequently the computation of left and right least common multiples, rightLcm and leftLcm.

```
  e := leftGcd(a,b)
      2 2        1
    3x D  + 2D + -
               x
     Type: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer)
```

Note that a greatest common divisor doesn't necessarily divide a and b on both sides. Here the left greatest common divisor does not divide a on the right.

```
  leftRemainder(a, e)
    0
```

```
     Type: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer)

  rightRemainder(a, e)
         5
    10D + -
         x
     Type: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer)
```

Similarly, a least common multiple is not necessarily divisible from both sides.

```
  f := rightLcm(a,b)
       3 3       2        2         7
    15x D  + (51x  + 10x)D  + 29D + -
     Type: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer)

  rightRemainder(f, b)
         5
    10D + -
         x
     Type: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer)

  leftRemainder(f, b)
    0
     Type: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer)
```

— LinearOrdinaryDifferentialOperator2.help —

```
=====================================================================
LinearOrdinaryDifferentialOperator2
=====================================================================
```

```
LinearOrdinaryDifferentialOperator2(A, M) is the domain of linear
ordinary differential operators with coefficients in the differential
ring A and operating on M, an A-module.  This includes the cases of
operators which are polynomials in D acting upon scalar or vector
expressions of a single variable.  The coefficients of the operator
polynomials can be integers, rational functions, matrices or elements
of other domains.

========================================================================
Differential Operators with Constant Coefficients
========================================================================

This example shows differential operators with rational number
coefficients operating on univariate polynomials.

We begin by making type assignments so we can conveniently refer
to univariate polynomials in x over the rationals.

  Q  := Fraction Integer
    Fraction Integer
                          Type: Domain

  PQ := UnivariatePolynomial('x, Q)
    UnivariatePolynomial(x,Fraction Integer)
                          Type: Domain

  x: PQ := 'x
    x
                          Type: UnivariatePolynomial(x,Fraction Integer)

Now we assign Dx to be the differential operator D corresponding to d/dx.

  Dx: LODO2(Q, PQ) := D()
    D
     Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
             UnivariatePolynomial(x,Fraction Integer))

New operators are created as polynomials in D().

  a := Dx  + 1
    D + 1
     Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
             UnivariatePolynomial(x,Fraction Integer))

  b := a + 1/2*Dx**2 - 1/2
    1  2       1
    - D  + D + -
    2          2
      Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
              UnivariatePolynomial(x,Fraction Integer))
```

```
To apply the operator a to the value p the usual function call syntax
is used.

  p := 4*x**2 + 2/3
      2   2
    4x  + -
          3
                    Type: UnivariatePolynomial(x,Fraction Integer)

  a p
      2        2
    4x  + 8x + -
               3
                    Type: UnivariatePolynomial(x,Fraction Integer)

Operator multiplication is defined by the identity (a*b)p = a(b(p))

  (a * b) p = a b p
      2         37    2         37
    2x  + 12x + --= 2x  + 12x + --
                 3              3
                    Type: Equation UnivariatePolynomial(x,Fraction Integer)

Exponentiation follows from multiplication.

  c := (1/9)*b*(a + b)^2
      1  6    5  5   13  4   19  3   79  2    7     1
     -- D  + -- D  + -- D  + -- D  + -- D  + -- D + -
     72      36      24      18      72      12     8
      Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
              UnivariatePolynomial(x,Fraction Integer))

Finally, note that operator expressions may be applied directly.

  (a**2 - 3/4*b + c) (p + 1)
       2   44     541
     3x  + -- x + ---
            3      36
                    Type: UnivariatePolynomial(x,Fraction Integer)

========================================================================
Differential Operators with Matrix Coefficients Operating on Vectors}
========================================================================

This is another example of linear ordinary differential operators with
non-commutative multiplication.  Unlike the rational function case,
the differential ring of square matrices (of a given dimension) with
univariate polynomial entries does not form a field.  Thus the number
of operations available is more limited.
```

```
In this section, the operators have three by three matrix coefficients
with polynomial entries.

  PZ := UnivariatePolynomial(x,Integer)
    UnivariatePolynomial(x,Integer)
                            Type: Domain

  x:PZ := 'x
    x
                            Type: UnivariatePolynomial(x,Integer)

  Mat  := SquareMatrix(3,PZ)
    SquareMatrix(3,UnivariatePolynomial(x,Integer))
                            Type: Domain

The operators act on the vectors considered as a Mat-module.

  Vect := DPMM(3, PZ, Mat, PZ)
  DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatrix(3,Un
  ivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer))
                            Type: Domain

  Modo := LODO2(Mat, Vect)
  LinearOrdinaryDifferentialOperator2(SquareMatrix(3,UnivariatePolynomial(x,Int
  eger)),DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatr
  ix(3,UnivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer)))
                            Type: Domain

The matrix m is used as a coefficient and the vectors p and q are
operated upon.

  m:Mat := matrix [ [x^2,1,0],[1,x^4,0],[0,0,4*x^2] ]
        + 2         +
        |x   1    0 |
        |           |
        |     4     |
        |1   x    0 |
        |           |
        |          2|
        +0   0   4x +
                          Type: SquareMatrix(3,UnivariatePolynomial(x,Integer))

  p:Vect := directProduct [3*x^2+1,2*x,7*x^3+2*x]
       2          3
    [3x  + 1,2x,7x  + 2x]
    Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
              SquareMatrix(3,UnivariatePolynomial(x,Integer)),
                 UnivariatePolynomial(x,Integer))
```

```
  q: Vect := m * p
       4    2        5     2        5     3
    [3x  + x  + 2x,2x  + 3x  + 1,28x  + 8x ]
      Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
         SquareMatrix(3,UnivariatePolynomial(x,Integer)),
            UnivariatePolynomial(x,Integer))
```

Now form a few operators.

```
  Dx : Modo := D()
    D
      Type: LinearOrdinaryDifferentialOperator2(
             SquareMatrix(3,UnivariatePolynomial(x,Integer)),
             DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
             SquareMatrix(3,UnivariatePolynomial(x,Integer)),
             UnivariatePolynomial(x,Integer)))

  a : Modo := Dx  + m
              + 2         +
              |x   1    0 |
              |           |
         D + |     4     |
              |1   x    0 |
              |           |
              |          2|
              +0   0   4x +
    Type: LinearOrdinaryDifferentialOperator2(
             SquareMatrix(3,UnivariatePolynomial(x,Integer)),
             DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
             SquareMatrix(3,UnivariatePolynomial(x,Integer)),
             UnivariatePolynomial(x,Integer)))

  b : Modo := m*Dx  + 1
         + 2         +
         |x   1    0 |    +1  0  0+
         |           |    |       |
         |     4     |D + |0  1  0|
         |1   x    0 |    |       |
         |           |    +0  0  1+

========================================================================
List examples
========================================================================

A list is a finite collection of elements in a specified order that
can contain duplicates.  A list is a convenient structure to work with
because it is easy to add or remove elements and the length need not
be constant.  There are many different kinds of lists in Axiom, but
the default types (and those used most often) are created by the List
constructor.  For example, there are objects of type List Integer,
List Float and List Polynomial Fraction Integer.  Indeed, you can even
have List List List Boolean (that is, lists of lists of lists of
Boolean values).  You can have lists of any type of Axiom object.

========================================================================
Creating Lists
========================================================================

The easiest way to create a list with, for example, the elements
2, 4, 5, 6 is to enclose the elements with square brackets and
separate the elements with commas.

The spaces after the commas are optional, but they do improve the
readability.

  [2, 4, 5, 6]
    [2,4,5,6]
                          Type: List PositiveInteger

To create a list with the single element 1, you can use either [1] or
the operation list.

  [1]
    [1]
                          Type: List PositiveInteger
```

```
  list(1)
    [1]
                          Type: List PositiveInteger
```

Once created, two lists k and m can be concatenated by issuing append(k,m). append does not physically join the lists, but rather produces a new list with the elements coming from the two arguments.

```
  append([1,2,3],[5,6,7])
    [1,2,3,5,6,7]
                          Type: List PositiveInteger
```

Use cons to append an element onto the front of a list.

```
  cons(10,[9,8,7])
    [10,9,8,7]
                          Type: List PositiveInteger
```

```
========================================================================
Accessing List Elements
========================================================================
```

To determine whether a list has any elements, use the operation empty?.

```
  empty? [x+1]
    false
                          Type: Boolean
```

Alternatively, equality with the list constant nil can be tested.

```
  ([] = nil)@Boolean
    true
                          Type: Boolean
```

We'll use this in some of the following examples.

```
  k := [4,3,7,3,8,5,9,2]
    [4,3,7,3,8,5,9,2]
                          Type: List PositiveInteger
```

Each of the next four expressions extracts the first element of k.

```
  first k
    4
                          Type: PositiveInteger

  k.first
    4
                          Type: PositiveInteger
```

```
  k.1
    4
                            Type: PositiveInteger

  k(1)
    4
                            Type: PositiveInteger
```

The last two forms generalize to k.i and k(i), respectively, where 1 <= i <= n and n equals the length of k.

This length is calculated by #.

```
  n := #k
    8
                            Type: PositiveInteger
```

Performing an operation such as k.i is sometimes referred to as indexing into k or elting into k. The latter phrase comes about because the name of the operation that extracts elements is called elt. That is, k.3 is just alternative syntax for elt(k,3). It is important to remember that list indices begin with 1. If we issue k := [1,3,2,9,5] then k.4 returns 9. It is an error to use an index that is not in the range from 1 to the length of the list.

The last element of a list is extracted by any of the following three expressions.

```
  last k
    2
                                Type: PositiveInteger

  k.last
    2
                                Type: PositiveInteger
```

This form computes the index of the last element and then extracts the element from the list.

```
  k.(#k)
    2
                                Type: PositiveInteger
```

```
========================================================================
Changing List Elements
========================================================================
```

We'll use this in some of the following examples.

```
  k := [4,3,7,3,8,5,9,2]
    [4,3,7,3,8,5,9,2]
                              Type: List PositiveInteger
```

List elements are reset by using the k.i form on the left-hand side of an assignment. This expression resets the first element of k to 999.

```
  k.1 := 999
    999
                              Type: PositiveInteger
```

As with indexing into a list, it is an error to use an index that is not within the proper bounds. Here you see that k was modified.

```
  k
    [999,3,7,3,8,5,9,2]
                              Type: List PositiveInteger
```

The operation that performs the assignment of an element to a particular position in a list is called setelt. This operation is destructive in that it changes the list. In the above example, the assignment returned the value 999 and k was modified. For this reason, lists are called mutable objects: it is possible to change part of a list (mutate it) rather than always returning a new list reflecting the intended modifications.

Moreover, since lists can share structure, changes to one list can sometimes affect others.

```
  k := [1,2]
    [1,2]
                              Type: List PositiveInteger

  m := cons(0,k)
    [0,1,2]
                              Type: List Integer
```

Change the second element of m.

```
  m.2 := 99
    99
                              Type: PositiveInteger
```

See, m was altered.

```
  m
    [0,99,2]
                              Type: List Integer
```

But what about k? It changed too!

```
  k
    [99,2]
                                Type: List PositiveInteger

========================================================================
Other Functions
========================================================================

An operation that is used frequently in list processing is that
which returns all elements in a list after the first element.

  k := [1,2,3]
    [1,2,3]
                                Type: List PositiveInteger

Use the rest operation to do this.

  rest k
    [2,3]
                                Type: List PositiveInteger

To remove duplicate elements in a list k, use removeDuplicates.

  removeDuplicates [4,3,4,3,5,3,4]
    [4,3,5]
                                Type: List PositiveInteger

To get a list with elements in the order opposite to those in a list
k, use reverse.

  reverse [1,2,3,4,5,6]
    [6,5,4,3,2,1]
                                Type: List PositiveInteger

To test whether an element is in a list, use member?: member?(a,k)
returns true or false depending on whether a is in k or not.

  member?(1/2,[3/4,5/6,1/2])
    true
                                Type: Boolean

  member?(1/12,[3/4,5/6,1/2])
    false
                                Type: Boolean

We can get a list containing all but the last of the elements in a
given non-empty list k.

  reverse(rest(reverse(k)))
```

```
    [1,2]
                                Type: List PositiveInteger

========================================================================
Dot, Dot
========================================================================

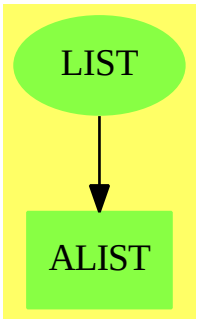
Certain lists are used so often that Axiom provides an easy way of
constructing them.  If n and m are integers, then expand [n..m]
creates a list containing n, n+1, ... m.  If n > m then the list is
empty.  It is actually permissible to leave off the m in the dot-dot
construction (see below).

The dot-dot notation can be used more than once in a list construction
and with specific elements being given.  Items separated by dots are
called segments.

  [1..3,10,20..23]
    [1..3,10..10,20..23]
                                Type: List Segment PositiveInteger

Segments can be expanded into the range of items between the endpoints
by using expand.

  expand [1..3,10,20..23]
    [1,2,3,10,20,21,22,23]
                                Type: List Integer



What happens if we leave off a number on the right-hand side of ..?

  expand [1..]
    [1,2,3,4,5,6,7,8,9,10,...]
                                Type: Stream Integer

What is created in this case is a Stream which is a generalization of
a list.

— domain LIST List —

```
)abbrev domain LIST List
++ Author: Michael Monagan
++ Date Created: Sep 1987
++ Description:
```

```
++ \spadtype{List} implements singly-linked lists that are
++ addressable by indices; the index of the first element
++ is 1. In addition to the operations provided by
++ \spadtype{IndexedList}, this constructor provides some
++ LISP-like functions such as \spadfun{null} and \spadfun{cons}.

List(S:Type): Exports == Implementation where
 LISTMININDEX ==> 1       -- this is the minimum list index

 Exports ==> ListAggregate S with
  nil             : ()     -> %
    ++ nil() returns the empty list.
  null            : %      -> Boolean
    ++ null(u) tests if list \spad{u} is the
    ++ empty list.
  cons            : (S, %) -> %
    ++ cons(element,u) appends \spad{element} onto the front
    ++ of list \spad{u} and returns the new list. This new list
    ++ and the old one will share some structure.
  append          : (%, %) -> %
    ++ append(u1,u2) appends the elements of list \spad{u1}
    ++ onto the front of list \spad{u2}. This new list
    ++ and \spad{u2} will share some structure.
  if S has SetCategory then
    setUnion        : (%, %) -> %
      ++ setUnion(u1,u2) appends the two lists u1 and u2, then
      ++ removes all duplicates. The order of elements in the
      ++ resulting list is unspecified.
    setIntersection : (%, %) -> %
      ++ setIntersection(u1,u2) returns a list of the elements
      ++ that lists \spad{u1} and \spad{u2} have in common.
      ++ The order of elements in the resulting list is unspecified.
    setDifference   : (%, %) -> %
      ++ setDifference(u1,u2) returns a list of the elements
      ++ of \spad{u1} that are not also in \spad{u2}.
      ++ The order of elements in the resulting list is unspecified.
  if S has OpenMath then OpenMath

 Implementation ==>

— domain LMOPS ListMonoidOps —

```
)abbrev domain LMOPS ListMonoidOps
++ Author: Manuel Bronstein
++ Date Created: November 1989
++ Date Last Updated: 6 June 1991
++ Description:
++ This internal package represents monoid (abelian or not, with or
++ without inverses) as lists and provides some common operations
++ to the various flavors of monoids.

ListMonoidOps(S, E, un): Exports == Implementation where
  S : SetCategory
  E : AbelianMonoid
  un: E

  REC ==> Record(gen:S, exp: E)
  O   ==> OutputForm

  Exports ==> Join(SetCategory, RetractableTo S) with
    outputForm    : ($, (O, O) -> O, (O, O) -> O, Integer) -> O
```

```
    ++ outputForm(l, fop, fexp, unit) converts the monoid element
    ++ represented by l to an \spadtype{OutputForm}.
    ++ Argument unit is the output form
    ++ for the \spadignore{unit} of the monoid (e.g. 0 or 1),
    ++ \spad{fop(a, b)} is the
    ++ output form for the monoid operation applied to \spad{a} and b
    ++ (e.g. \spad{a + b}, \spad{a * b}, \spad{ab}),
    ++ and \spad{fexp(a, n)} is the output form
    ++ for the exponentiation operation applied to \spad{a} and n
    ++ (e.g. \spad{n a}, \spad{n * a}, \spad{a ** n}, \spad{a\^n}).
  listOfMonoms  : $ -> List REC
    ++ listOfMonoms(l) returns the list of the monomials forming l.
  makeTerm      : (S, E) -> $
    ++ makeTerm(s, e) returns the monomial s exponentiated by e
    ++ (e.g. s^e or e * s).
  makeMulti     : List REC -> $
    ++ makeMulti(l) returns the element whose list of monomials is l.
  nthExpon      : ($, Integer) -> E
    ++ nthExpon(l, n) returns the exponent of the n^th monomial of l.
  nthFactor     : ($, Integer) -> S
    ++ nthFactor(l, n) returns the factor of the n^th monomial of l.
  reverse       : $ -> $
    ++ reverse(l) reverses the list of monomials forming l. This
    ++ has some effect if the monoid is non-abelian, i.e.
    ++ \spad{reverse(a1\^e1 ... an\^en) = an\^en ... a1\^e1} which is different.
  reverse_!     : $ -> $
    ++ reverse!(l) reverses the list of monomials forming l, destroying
    ++ the element l.
  size          : $ -> NonNegativeInteger
    ++ size(l) returns the number of monomials forming l.
  makeUnit      : () -> $
    ++ makeUnit() returns the unit element of the monomial.
  rightMult     : ($, S) -> $
    ++ rightMult(a, s) returns \spad{a * s} where \spad{*}
    ++ is the monoid operation,
    ++ which is assumed non-commutative.
  leftMult      : (S, $) -> $
    ++ leftMult(s, a) returns \spad{s * a} where
    ++ \spad{*} is the monoid operation,
    ++ which is assumed non-commutative.
  plus          : (S, E, $) -> $
    ++ plus(s, e, x) returns \spad{e * s + x} where \spad{+}
    ++ is the monoid operation,
    ++ which is assumed commutative.
  plus          : ($, $) -> $
    ++ plus(x, y) returns \spad{x + y} where \spad{+}
    ++ is the monoid operation,
    ++ which is assumed commutative.
  commutativeEquality: ($, $) -> Boolean
    ++ commutativeEquality(x,y) returns true if x and y are equal
```

```
    ++ assuming commutativity
  mapExpon      : (E -> E, $) -> $
    ++ mapExpon(f, a1\^e1 ... an\^en) returns \spad{a1\^f(e1) ... an\^f(en)}.
  mapGen        : (S -> S, $) -> $
    ++ mapGen(f, a1\^e1 ... an\^en) returns \spad{f(a1)\^e1 ... f(an)\^en}.

========================================================================
LyndonWord examples
========================================================================

A function f in [0,1] is called acyclic if C(F) consists of n
```

```
different objects. The canonical representative of the orbit of an
acyclic function is usually called a Lyndon Word. If f is acyclic,
then all elements in the orbit C(f) are acyclic as well, and we call
C(f) an acyclic orbit.

++ Author: Michel Petitot (petitot@lifl.fr).
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ References:
++ Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ Description:
++ Lyndon words over arbitrary (ordered) symbols:
++ see Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ A Lyndon word is a word which is smaller than any of its right factors
++ w.r.t. the pure lexicographical ordering.
++ If \axiom{a} and \axiom{b} are two Lyndon words such that \axiom{a < b}
++ holds w.r.t lexicographical ordering then \axiom{a*b} is a Lyndon word.
++ Parenthesized Lyndon words can be generated from symbols by using the
++ following rule:\br
++ \axiom{[[a,b],c]} is a Lyndon word iff \axiom{a*b < c <= b} holds.\br
++ Lyndon words are internally represented by binary trees using the
++ \spadtype{Magma} domain constructor.
++ Two ordering are provided: lexicographic and
++ length-lexicographic.

LyndonWord(VarSet:OrderedSet):Public == Private where
   OFMON ==> OrderedFreeMonoid(VarSet)

++ Author: Michel Petitot (petitot@lifl.fr).
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ Description:
++ This type is the basic representation of
++ parenthesized words (binary trees over arbitrary symbols)
++ useful in \spadtype{LiePolynomial}.

Magma(VarSet:OrderedSet):Public == Private where
   WORD ==> OrderedFreeMonoid(VarSet)
   EX   ==> OutputForm

   Public == Join(OrderedSet,RetractableTo VarSet) with
```

```
    "*"           : ($,$) -> $
      ++ \axiom{x*y} returns the tree \axiom{[x,y]}.
    coerce        : $ -> WORD
      ++ \axiom{coerce(x)} returns the element of
      ++\axiomType{OrderedFreeMonoid}(VarSet)
      ++ corresponding to \axiom{x} by removing parentheses.
    first         : $ -> VarSet
      ++ \axiom{first(x)} returns the first entry of the tree \axiom{x}.
    left          : $ -> $
      ++ \axiom{left(x)} returns left subtree of \axiom{x} or
      ++ error if retractable?(x) is true.
    length        : $ -> PositiveInteger
      ++ \axiom{length(x)} returns the number of entries in \axiom{x}.
    lexico        : ($,$) -> Boolean
      ++ \axiom{lexico(x,y)} returns \axiom{true} iff  \axiom{x} is smaller
      ++ than \axiom{y} w.r.t. the lexicographical ordering induced by
      ++ \axiom{VarSet}.
      ++ N.B. This operation does not take into account the tree structure of
      ++ its arguments. Thus this is not a total ordering.
    mirror        : $ -> $
      ++ \axiom{mirror(x)} returns the reversed word of \axiom{x}.

MathMLFormat examples
=====================================================================

This package is based on the TeXFormat domain by Robert S. Sutor
MathMLFormat provides a coercion from OutputForm to MathML format.

See Also:
o )show MathMLFormat
```

———-

Both this code and documentation are still under development and I don't pretend they are anywhere close to perfect or even finished. However the code does work and I hope it might be useful to somebody both for it's ability to output MathML from Axiom and as an example of how to write a new output form.

Introduction to Mathematical Markup Language

MathML exists in two forms: presentation and content. At this time (2007-02-11) the package only has a presentation package. A content package is in the works however it is more difficult. Unfortunately Axiom does not make its semantics easily available. The OutputForm domain mediates between the individual Axiom domains and the user visible output but OutputForm does not provide full semantic information. From my currently incomplete understanding of Axiom it appears that remedying this would entail going back to the individual domains and rewriting a lot of code. However some semantics are conveyed directly by OutputForm and other things can be deduced from OutputForm or from the original user command.

Displaying MathML

The MathML string produced by ")set output mathml on" can be pasted directly into an appropriate xhtml page and then viewed in Firefox or some other MathML aware browser. The boiler plate code needed for a test page, testmathml.xml, is:

```
<?xml version="1.0" ?>
```

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 plus MathML 2.0//EN"
                      "http://www.w3.org/Math/DTD/mathml2/xhtml-math11-f.dtd" [
<!ENTITY mathml "http://www.w3.org/1998/Math/MathML">
]>

<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:xlink="http://www.w3.org/1999/xlink" >

  <head>
    <title>MathML Test </title>
  </head>

  <body>

  </body>
</html>
```

Paste the MathML string into the body element and it should display nicely in Firefox.

Test Cases

Here's a list of test cases that currently format correctly:

1. (x+y)**2
2. integrate(x**x,x)
3. integral(x**x,x)
4. (5 + sqrt 63 + sqrt 847)**(1/3)
5. set [1,2,3]
6. multiset [x rem 5 for x in primes(2,1000)]
7. series(sin(a*x),x=0)
8. matrix [[x**i + y**j for i in 1..10] for j in 1..10]
9. y := operator 'y a. D(y(x,z),[x,x,z,x]) b. D(y x,x,2)
10. x := series 'x a. sin(1+x)
11. series(1/log(y),y=1)
12. y:UTS(FLOAT,'z,0) := exp(z)
13. a. c := continuedFraction(314159/100000) b. c := continuedFraction(314159/100000)

The TexFormat domain has the capability to format an object with subscripts, superscripts, presubscripts and presuperscripts however I don't know of any Axiom command that produces such an object. In fact at present I see the case of "SUPERSUB" being used for putting primes in the superscript position to denote ordinary differentiation. I also only see the "SUB" case being used to denote partial derivatives.

)set output mathml on

Making mathml appear as output during a normal Axiom session by invoking ")set output mathml on" proved to be a bit tedious and seems to be undocumented. I document my experience here in case it proves useful to somebody else trying to get a new output format from Axiom.

In MathMLFormat the functions **coerce(expr : OutputForm) : String** and **display(s : String) : Void** provide the desired mathml output. Note that this package was constructed by close examination of Robert Sutor's TexFormat domain and much remains from that source. To have mathml displayed as output we need to get Axiom to call display(coerce(expr)) at the appropriate place. Here's what I did to get that to happen. Note that my starting point here was an attempt by Andrey Grozin to do the same. To figure things out I searched through files for "tex" to see what was done for the TexFormat domain, and used grep to find which files had mention of TexFormat.

File src/interp/setvars.boot.pamphlet

Create an output mathml section by analogy to the tex section. Remember to add the code chunk "outputmathmlCode" at the end.

setvars.boot is a bootstrap file which means that it has to be precompiled into lisp code and then that code has to be inserted back into setvars.boot. To do this extract the boot code by running "notangle" on it. I did this from the "tmp" directory. From inside axiom run ")lisp (boottran::boottocl "tmp/setvars.boot") which put "setvars.clisp" into "int/interp/setvars.clisp". Then replace the lisp in "setvars.boot.pamphlet" with that in the newly generated "setvars.clisp".

The relevant code chunks appearing in "setvars.boot.pamphlet" are:

```
outputmathmlCode
setOutputMathml
describeSetOutputMathml
```

and the relevant variables are:

```
setOutputMathml
$mathmlOutputStream
$mathmlOutputFile
$mathmlFormat
describeSetOutputMathml
```

File setvart.boot.pamphlet

Create an output mathml section in "setvart.boot.pamphlet" again patterned after the tex section. I changed the default file extension from ".stex" to ".smml".

To the "sectionoutput" table I added the line

```
mathml                    created output in MathML style      Off:CONSOLE
```

Added the code chunk "outputmathml" to the code chunk "output" in "sectionoutput".

Relevant code chunks:

```
outputmathml
```

Relevant variables:

```
setOutputMathml
$mathmlFormat
$mathmlOutputFile
```

Note when copying the tex stuff I changed occurrences of "tex" to "mathml", "Tex" to "Mathml" and "TeX" to "MathML".

File src/algebra/Makefile.pamphlet

The file "src/algebra/tex.spad.pamphlet" contains the domain TexFormat (TEX) and the package TexFormat1 (TEX1). However the sole function of TexFormat1 is to **coerce** objects from a domain into OutputForm and then apply TexFormat to them. It is to save programmers the trouble of doing the coercion themselves from inside spad code. It does not appear to be used for the main purpose of delivering Axiom output in TeX format. In order to keep the mathml package as simple as possible, and because I didn't see much use for this, I didn't copy the TexFormat1 package. So no analog of the TEX1 entries in "Makefile.pamphlet" were needed. One curiosity I don't understand is why TEX1 appears in layer 4 when it seems to depend on TEX which appears in layer 14.

Initially I added "$OUT/MMLFORM.o" to layer 14 and "mathml.spad.pamphlet" to completed spad files in layer 14. When trying to compile the build failed at MMLFORM. It left "MMLFORM.erlib" in "int/algebra" instead of "MMLFORM.NRLIB" which confused me at first because mathml.spad compiled under a running axiom. By examining the file "obj/tmp/trace" I saw that a new dependency had been introduced, compared to TexFormat, with the function eltName depending on the domain FSAGG in layer 16. So the lines had to be moved from layer 14 to layer 17.

Added appropriate lines to "SPADFILES" and "DOCFILES".

File src/algebra/exposed.lsp.pamphlet

Add the line "(|MathMLFormat| . MMLFORM)"

File src/algebra/Lattice.pamphlet

I don't see that this file is used anywhere but I made the appropriate changes anyway by searching for "TEX" and mimicing everything for MMLFORM.

File src/doc/axiom.bib.pamphlet

Added mathml.spad subsection to "src/doc/axiom.bib.pamphlet".

File interp/i-output.boot.pamphlet

This is where the **coerce** and **display** functions from MathMLFormat actually get called. The following was added:

```
mathmlFormat expr ==
  mml := '(MathMLFormat)
  mmlrep := '(String)
  formatFn := getFunctionFromDomain("coerce",mml,[$OutputForm])
  displayFn := getFunctionFromDomain("display",mml,[mmlrep])
  SPADCALL(SPADCALL(expr,formatFn),displayFn)
  TERPRI $mathmlOutputStream
  FORCE_-OUTPUT $mathmlOutputStream
  NIL
```

Note that compared to the texFormat function there are a couple of differences. Since MathMLFormat is currently a package rather than a domain there is the "mmlrep" variable whereas in texFormat the argument of the "display" function is an instance of the domain. Also the **coerce** function here only has one argument, namely "$OutputForm".

Also for the function "output(expr,domain)" add lines for mathml, e.g. "if $mathmlFormat then mathmlFormat expr".

After these changes Axiom compiled with mathml enabled under)set output.

Public Declarations

The declarations

```
  E      ==> OutputForm
  I      ==> Integer
  L      ==> List
  S      ==> String
  US     ==> UniversalSegment(Integer)
```

provide abbreviations for domains used heavily in the code. The publicly exposed functions are:

coerce: E -> S This function is the main one for converting an expression in domain OutputForm into a MathML string.

coerceS: E -> S This function is for use from the command line. It converts an OutputForm expression into a MathML string and does some formatting so that the output is not one long line. If you take the output from this function, stick it in an emacs buffer in nxml-mode

and then indent according to mode, you'll get something that's nicer to look at than what comes from coerce. Note that coerceS returns the same value as coerce but invokes a display function as well so that the result will be printed twice in different formats. The need for this is that the output from coerce is automatically formatted with line breaks by Axiom's output routine that are not in the right place.

coerceL: E -> S Similar to coerceS except that the displayed result is the MathML string in one long line. These functions can be used, for instance, to get the MathML for the previous result by typing coerceL(

exprex: E -> S Converts OutputForm to String with the structure preserved with braces. This is useful in developing this package. Actually this is not quite accurate. The function **precondition** is first applied to the OutputForm expression before **exprex**. Raw OutputForm and the nature of the **precondition** function is still obscure to me at the time of this writing (2007-02-14), however I probably need to understand it to make sure I'm not missing any semantics. The spad function **precondition** is just a wrapper for the lisp function outputTran$Lisp, which I guess is compiled from boot.

display: S -> Void This one prints the string returned by coerce as one long line, adding "math" tags: $...$. Thus the output from this can be stuck directly into an appropriate html/xhtml page and will be displayed nicely by a MathML aware browser.

displayF: S -> Void This function doesn't exist yet but it would be nice to have a humanly readable formatted output as well. The basics do exist in the coerceS function however the formatting still needs some work to be really good.

Private Function Declarations

These are the local functions:

addBraces:S -> S

addBrackets:S -> S

atomize:E -> L E

displayElt:S -> Void function for recursively displaying mathml nicely formatted

eltLimit:(S,I,S) -> I demarcates end postion of mathml element with name:S starting at position i:I in mathml string s:S and returns end of end tag as i:I position in mathml string, i.e. find start and end of substring: <name ...>...</name>

eltName:(I,S) -> S find name of mathml element starting at position i:I in string s:S

group:S -> S

formatBinary:(S,L E, I) -> S

formatFunction:(S,L E, I) -> S

formatMatrix:L E -> S

formatNary:(S,L E, I) -> S

formatNaryNoGroup:(S,L E, I) -> S

formatNullary:S -> S

formatPlex:(S,L E, I) -> S

formatSpecial:(S,L E, I) -> S

formatUnary:(S, E, I) -> S

formatMml:(E,I) -> S

newWithNum:I -> $ this is a relic from tex.spad and is not used here so far. I'll probably remove it.

parenthesize:S -> S

precondition:E -> E this function is applied to the OutputForm expression before doing anything else.

postcondition:S -> S this function is applied after all other OutputForm -> MathML transformations. In the TexFormat domain the ungroup function first peels off the outermost set of braces however I have replaced braces with <mrow>s here and sometimes the outermost set of <mrow>s is necessary to get proper display in Firefox. For instance with getting the correct size of brackets on a matrix the whole expression needs to be enclosed in a mrow element. It also checks for +− and removes the +.

stringify:E -> S

tagEnd:(S,I,S) -> I finds closing ">" of start or end tag for mathML element for formatting MathML string for human readability. No analog in TexFormat.

ungroup:S -> S

Public Function Definitions

Note that I use the function sayTeX$Lisp much as I would printf in a C program. I've noticed in grepping the code that there are other "say" functions, sayBrightly and sayMessage for instance, but I have no idea what the difference is between them at this point. sayTeX$Lisp does the job so for the time being I'll use that until I learn more.

The functions coerceS and coerceL should probably be changed to display functions, *i.e.* **displayS** and **display L**, returning Void. I really only need the one coerce function.

— **public function definitions** —

```

Formatting Functions

Still need to format `\zag` in formatSpecial!

In formatPlex the case op = "INTSIGN" is now passed off to formatIntSign which is a change from the TexFormat domain. This is done here for presentation mark up to replace the ugly bound variable that Axiom delivers. For content mark up this has to be done anyway.

The formatPlex function also allows for op = "INDEFINTEGRAL". However I don't know what Axiom command gives rise to this case. The INTSIGN case already allows for both definite and indefinite integrals.

In the function formatSpecial various cases are handled including SUB and SUPERSUB. These cases are now caught in formatMml and so the code in formatSpecial doesn't get executed. The only cases I know of using these are partial derivatives for SUB and ordinary derivatives or SUPERSUB however in TexFormat the capability is there to handle multiscripts, i.e. an object with subscripts, superscripts, pre-subscripts and pre-superscripts but I am so far unaware of any Axiom command that produces such a multiscripted object.

Another question is how to represent derivatives. At present I have differential notation for partials and prime notation for ordinary derivatives, but it would be nice to allow for different derivative notations in different circumstances, maybe some options to)set output mathml on.

Ordinary derivatives are formatted in formatSuperSub and there are 2 versions, formatSuperSub and formatSuperSub1, which at this point have to be switched by swapping names.

========================================================================
MathMLFormat examples
========================================================================

MathML is an HTML-like markup language for mathematics. It uses the
"knuckle" syntax of HTML such as "<mo>" to introduce a math operator
and "</mo>" to mark the end of the operator. Axiom can generate
MathML output and does so when it communicates to the browser front end.

This output is enabled by

  )set output mathml on

after which you'll see the MathML markup as well as the algebra.
Note that you can turn off the algebra output with

  )set output algebra off

but we don't do that here so you can compare the output.

```
=====================================================================
Matrix examples
=====================================================================

The Matrix domain provides arithmetic operations on matrices
and standard functions from linear algebra.
This domain is similar to the TwoDimensionalArray domain, except
that the entries for Matrix must belong to a  Ring.

=====================================================================
Creating Matrices
=====================================================================

There are many ways to create a matrix from a collection of values or
from existing matrices.

If the matrix has almost all items equal to the same value, use new to
create a matrix filled with that value and then reset the entries that
are different.
```

```
  m : Matrix(Integer) := new(3,3,0)
    +0  0  0+
    |       |
    |0  0  0|
    |       |
    +0  0  0+
                        Type: Matrix Integer
```

To change the entry in the second row, third column to 5, use setelt.

```
  setelt(m,2,3,5)
    5
                        Type: PositiveInteger
```

An alternative syntax is to use assignment.

```
  m(1,2) := 10
    10
                        Type: PositiveInteger
```

The matrix was destructively modified.

```
  m
    +0  10  0+
    |        |
    |0  0   5|
    |        |
    +0  0   0+
                        Type: Matrix Integer
```

If you already have the matrix entries as a list of lists, use matrix.

```
  matrix [ [1,2,3,4],[0,9,8,7] ]
    +1  2  3  4+
    |          |
    +0  9  8  7+
                        Type: Matrix Integer
```

If the matrix is diagonal, use diagonalMatrix.

```
  dm := diagonalMatrix [1,x**2,x**3,x**4,x**5]
        +1  0   0   0   0 +
        |                  |
        |   2              |
        |0  x   0   0   0  |
        |                  |
        |       3          |
        |0  0   x   0   0  |
        |                  |
        |           4      |
```

```
       |0  0   0   x   0 |
       |                 |
       |                5|
       +0  0   0   0   x +
                    Type: Matrix Polynomial Integer
```

Use setRow and setColumn to change a row or column of a matrix.

```
  setRow!(dm,5,vector [1,1,1,1,1])
       +1  0   0   0   0+
       |                 |
       |    2            |
       |0  x   0   0   0|
       |                 |
       |        3        |
       |0  0   x   0   0|
       |                 |
       |            4    |
       |0  0   0   x   0|
       |                 |
       +1  1   1   1   1+
                   Type: Matrix Polynomial Integer

  setColumn!(dm,2,vector [y,y,y,y,y])
       +1  y  0   0   0+
       |                |
       |0  y  0   0   0|
       |                |
       |       3        |
       |0  y  x   0   0|
       |                |
       |           4    |
       |0  y  0   x   0|
       |                |
       +1  y  1   1   1+
                    Type: Matrix Polynomial Integer
```

Use copy to make a copy of a matrix.

```
  cdm := copy(dm)
       +1  y  0   0   0+
       |                |
       |0  y  0   0   0|
       |                |
       |       3        |
       |0  y  x   0   0|
       |                |
       |           4    |
       |0  y  0   x   0|
       |                |
```

```
       +1  y  1   1   1+
                  Type: Matrix Polynomial Integer
```

This is useful if you intend to modify a matrix destructively but want a copy of the original.

```
  setelt(dm,4,1,1-x**7)
        7
     - x  + 1
                  Type: Polynomial Integer

  [dm,cdm]
          +   1      y  0   0   0+ +1  y  0   0   0+
          |                       | |               |
          |   0      y  0   0   0| |0  y  0   0   0|
          |                       | |               |
          |              3        | |       3       |
         [|   0      y  x   0   0|,|0  y  x   0   0|]
          |                       | |               |
          |   7               4   | |           4   |
          |- x  + 1  y  0   x   0| |0  y  0   x   0|
          |                       | |               |
          +   1      y  1   1   1+ +1  y  1   1   1+
                  Type: List Matrix Polynomial Integer
```

Use subMatrix to extract part of an existing matrix. The syntax is subMatrix(m, firstrow, lastrow, firstcol, lastcol).

```
  subMatrix(dm,2,3,2,4)
         +y  0   0+
         |        |
         |    3   |
         +y  x   0+
                  Type: Matrix Polynomial Integer
```

To change a submatrix, use setsubMatrix.

```
  d := diagonalMatrix [1.2,-1.3,1.4,-1.5]
         +1.2   0.0   0.0   0.0 +
         |                      |
         |0.0  - 1.3  0.0   0.0 |
         |                      |
         |0.0   0.0   1.4   0.0 |
         |                      |
         +0.0   0.0   0.0  - 1.5+
                  Type: Matrix Float
```

If e is too big to fit where you specify, an error message is displayed. Use subMatrix to extract part of e, if necessary.

```
  e := matrix [ [6.7,9.11],[-31.33,67.19] ]
         +  6.7    9.11 +
         |              |
         +- 31.33  67.19+
                     Type: Matrix Float
```

This changes the submatrix of d whose upper left corner is at the first row and second column and whose size is that of e.

```
  setsubMatrix!(d,1,2,e)
         +1.2    6.7    9.11    0.0 +
         |                          |
         |0.0  - 31.33  67.19   0.0 |
         |                          |
         |0.0    0.0     1.4    0.0 |
         |                          |
         +0.0    0.0     0.0   - 1.5+
                       Type: Matrix Float

  d
         +1.2    6.7    9.11    0.0 +
         |                          |
         |0.0  - 31.33  67.19   0.0 |
         |                          |
         |0.0    0.0     1.4    0.0 |
         |                          |
         +0.0    0.0     0.0   - 1.5+
                        Type: Matrix Float
```

Matrices can be joined either horizontally or vertically to make new matrices.

```
  a := matrix [ [1/2,1/3,1/4],[1/5,1/6,1/7] ]
         +1  1  1+
         |-  -  -|
         |2  3  4|
         |       |
         |1  1  1|
         |-  -  -|
         +5  6  7+
                         Type: Matrix Fraction Integer

  b := matrix [ [3/5,3/7,3/11],[3/13,3/17,3/19] ]
         +3   3    3+
         |-   -   --|
         |5   7   11|
         |          |
         | 3   3   3|
         |--  --  --|
         +13  17  19+
```

```
                        Type: Matrix Fraction Integer
```

Use horizConcat to append them side to side. The two matrices must have the same number of rows.

```
  horizConcat(a,b)
         +1  1  1  3   3    3+
         |-  -  -  -   -   --|
         |2  3  4  5   7   11|
         |                   |
         |1  1  1   3   3   3|
         |-  -  -  --  --  --|
         +5  6  7  13  17  19+
                        Type: Matrix Fraction Integer
```

Use vertConcat to stack one upon the other. The two matrices must have the same number of columns.

```
  vab := vertConcat(a,b)
         +1   1   1 +
         |-   -   - |
         |2   3   4 |
         |          |
         |1   1   1 |
         |-   -   - |
         |5   6   7 |
         |          |
         |3   3    3|
         |-   -   --|
         |5   7   11|
         |          |
         | 3   3   3|
         |--  --  --|
         +13  17  19+
                        Type: Matrix Fraction Integer
```

The operation transpose is used to create a new matrix by reflection across the main diagonal.

```
  transpose vab
         +1  1  3    3+
         |-  -  -   --|
         |2  5  5   13|
         |            |
         |1  1  3    3|
         |-  -  -   --|
         |3  6  7   17|
         |            |
         |1  1   3   3|
         |-  -  --  --|
```

```
        +4  7  11  19+
                        Type: Matrix Fraction Integer

========================================================================
Operations on Matrices
========================================================================

Axiom provides both left and right scalar multiplication.

  m := matrix [ [1,2],[3,4] ]
        +1  2+
        |    |
        +3  4+
                          Type: Matrix Integer

  4 * m * (-5)
        +- 20  - 40+
        |          |
        +- 60  - 80+
                          Type: Matrix Integer

You can add, subtract, and multiply matrices provided, of course, that
the matrices have compatible dimensions.  If not, an error message is
displayed.

  n := matrix([ [1,0,-2],[-3,5,1] ])
        + 1   0  - 2+
        |           |
        +- 3  5   1 +
                          Type: Matrix Integer

This following product is defined but n * m is not.

  m * n
        +- 5  10   0 +
        |            |
        +- 9  20  - 2+
                          Type: Matrix Integer

The operations nrows and ncols return the number of rows and columns
of a matrix.  You can extract a row or a column of a matrix using the
operations row and column.  The object returned is a Vector.

Here is the third column of the matrix n.

  vec := column(n,3)
     [- 2,1]
                          Type: Vector Integer

You can multiply a matrix on the left by a "row vector" and on the right
```

```
by a "column vector".

  vec * m
     [1,0]
                          Type: Vector Integer

Of course, the dimensions of the vector and the matrix must be compatible
or an error message is returned.

  m * vec
    [0,- 2]
                          Type: Vector Integer

The operation inverse computes the inverse of a matrix if the matrix
is invertible, and returns "failed" if not.

This Hilbert matrix is invertible.

  hilb := matrix([ [1/(i + j) for i in 1..3] for j in 1..3])
         +1  1  1+
         |-  -  -|
         |2  3  4|
         |       |
         |1  1  1|
         |-  -  -|
         |3  4  5|
         |       |
         |1  1  1|
         |-  -  -|
         +4  5  6+
                          Type: Matrix Fraction Integer

  inverse(hilb)
         + 72    - 240   180 +
         |                   |
         |- 240   900   - 720|
         |                   |
         + 180   - 720   600 +
                          Type: Union(Matrix Fraction Integer,...)

This matrix is not invertible.

  mm := matrix([ [1,2,3,4], [5,6,7,8], [9,10,11,12], [13,14,15,16] ])
         +1   2   3   4 +
         |              |
         |5   6   7   8 |
         |              |
         |9   10  11  12|
         |              |
         +13  14  15  16+
```

```
                          Type: Matrix Integer

  inverse(mm)
     "failed"
                          Type: Union("failed",...)
```

The operation determinant computes the determinant of a matrix provided that the entries of the matrix belong to a CommutativeRing.

The above matrix mm is not invertible and, hence, must have determinant 0.

```
  determinant(mm)
    0
                          Type: NonNegativeInteger
```

The operation trace computes the trace of a square matrix.

```
  trace(mm)
    34
                          Type: PositiveInteger
```

The operation rank computes the rank of a matrix: the maximal number of linearly independent rows or columns.

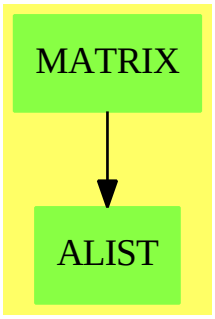
```
  rank(mm)
    2
                          Type: PositiveInteger
```

The operation nullity computes the nullity of a matrix: the dimension of its null space.

```
  nullity(mm)
    2
                          Type: PositiveInteger
```

The operation nullSpace returns a list containing a basis for the null space of a matrix. Note that the nullity is the number of elements in a basis for the null space.

```
  nullSpace(mm)
    [[1,- 2,1,0],[2,- 3,0,1]]
                          Type: List Vector Integer
```



The operation rowEchelon returns the row echelon form of a matrix. It is easy to see that the rank of this matrix is two and that its nullity is also two.

```
  rowEchelon(mm)
         +1  2  3  4 +
         |           |
```

```
                |0  4  8  12|
                |           |
                |0  0  0  0 |
                |           |
                +0  0  0  0 +
                                Type: Matrix Integer
```

```

— domain MATRIX Matrix —

```
)abbrev domain MATRIX Matrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{Matrix} is a matrix domain where 1-based indexing is used
++ for both rows and columns.

Matrix(R): Exports == Implementation where
  R : Ring
  Row ==> Vector R
  Col ==> Vector R
  mnRow ==> 1
  mnCol ==> 1
  MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)
  MATSTOR ==> StorageEfficientMatrixOperations(R)

  Exports ==> MatrixCategory(R,Row,Col) with
    diagonalMatrix: Vector R -> $
      ++ \spad{diagonalMatrix(v)} returns a diagonal matrix where the elements
      ++ of v appear on the diagonal.

    if R has ConvertibleTo InputForm then ConvertibleTo InputForm

    if R has Field then
      inverse: $ -> Union($,"failed")
        ++ \spad{inverse(m)} returns the inverse of the matrix m.
        ++ If the matrix is not invertible, "failed" is returned.
        ++ Error: if the matrix is not square.
--     matrix: Vector Vector R -> $
--       ++ \spad{matrix(v)} converts the vector of vectors v to a matrix, where
```

```
--       ++ the vector of vectors is viewed as a vector of the rows of the
--       ++ matrix
--     diagonalMatrix: Vector $ -> $
--       ++ \spad{diagonalMatrix([m1,...,mk])} creates a block diagonal matrix
--       ++ M with block matrices m1,...,mk down the diagonal,
--       ++ with 0 block matrices elsewhere.
--     vectorOfVectors: $ -> Vector Vector R
--       ++ \spad{vectorOfVectors(m)} returns the rows of the matrix m as a
--       ++ vector of vectors

  Implementation ==>

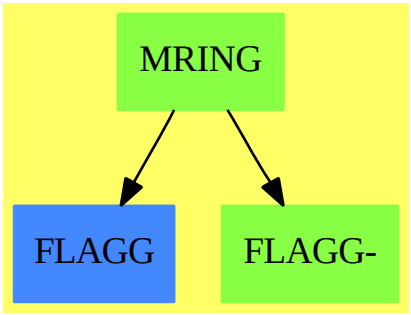
========================================================================
MonoidRing examples
========================================================================



MonoidRing(R,M), implements the algebra of all maps from the monoid M
to the commutative ring R with finite support.

Multiplication of two maps f and g is defined to map an element c of M
to the (convolution) sum over f(a)g(b) such that ab = c. Thus M can be
identified with a canonical basis and the maps can also be considered
as formal linear combinations of the elements in M. Scalar multiples
of a basis element are called monomials. A prominent example is the
class of polynomials where the monoid is a direct product of the
natural numbers with pointwise addition. When M is FreeMonoid Symbol,
one gets polynomials in infinitely many non-commuting variables.
Another application area is representation theory of finite
groups G, where modules over MonoidRing(R,G) are studied.

========================================================================
Multiset examples
========================================================================

The domain Multiset(R) is similar to Set(R) except that multiplicities
(counts of duplications) are maintained and displayed.  Use the
operation multiset to create multisets from lists.  All the standard
operations from sets are available for multisets.  An element with
multiplicity greater than one has the multiplicity displayed first,
then a colon, and then the element.

Create a multiset of integers.

  s := multiset [1,2,3,4,5,4,3,2,3,4,5,6,7,4,10]
    {1,2: 2,3: 3,4: 4,2: 5,6,7,10}
                          Type: Multiset PositiveInteger

The operation insert! adds an element to a multiset.

  insert!(3,s)
    {1,2: 2,4: 3,4: 4,2: 5,6,7,10}
                          Type: Multiset PositiveInteger

Use remove! to remove an element.  If a third argument is present, it
specifies how many instances to remove. Otherwise all instances of the
element are removed.  Display the resulting multiset.

  remove!(3,s,1); s

    {1,2: 2,3: 3,4: 4,2: 5,6,7,10}
                          Type: Multiset PositiveInteger
```

```
  remove!(5,s); s
    {1,2: 2,3: 3,4: 4,6,7,10}
                          Type: Multiset PositiveInteger
```

The operation count returns the number of copies of a given value.

```
  count(5,s)
    0
                          Type: NonNegativeInteger
```

A second multiset.

```
  t := multiset [2,2,2,-9]
    {3: 2,- 9}
                          Type: Multiset Integer
```

The union of two multisets is additive.

```
  U := union(s,t)
    {1,5: 2,3: 3,4: 4,6,7,10,- 9}
                          Type: Multiset Integer
```

The intersect operation gives the elements that are in common, with additive multiplicity.

```
  I := intersect(s,t)
    {5: 2}
                          Type: Multiset Integer
```

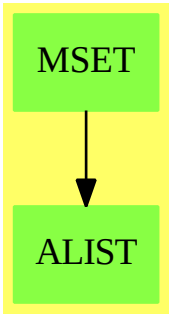
The difference of s and t consists of the elements that s has but t does not. Elements are regarded as indistinguishable, so that if s and t have any element in common, the difference does not contain that element.

```
  difference(s,t)
    {1,3: 3,4: 4,6,7,10}
                          Type: Multiset Integer
```

The symmetricDifference is the union of difference(s, t) and difference(t, s).

```
  S := symmetricDifference(s,t)
    {1,3: 3,4: 4,6,7,10,- 9}
                          Type: Multiset Integer
```

Check that the union of the symmetricDifference and the intersect equals the union of the elements.



```
  (U = union(S,I))@Boolean
    true
                          Type: Boolean
```

```
Check some inclusion relations.

  t1 := multiset [1,2,2,3]; [t1 < t, t1 < s, t < s, t1 <= s]
    [false,true,false,true]
                          Type: List Boolean

)abbrev domain MSET Multiset
++ Author:Stephen M. Watt, William H. Burge, Richard D. Jenks, Frederic Lehobey
++ Date Created:NK
++ Date Last Updated: 14 June 1994
++ Description:
```

```
++ A multiset is a set with multiplicities.

Multiset(S: SetCategory): MultisetAggregate S with
        finiteAggregate
        shallowlyMutable
        multiset: () -> %
          ++ multiset()$D creates an empty multiset of domain D.
        multiset: S -> %
          ++ multiset(s) creates a multiset with singleton s.
        multiset: List S -> %
          ++ multiset(ls) creates a multiset with elements from \spad{ls}.
        members: % -> List S
          ++ members(ms) returns a list of the elements of \spad{ms}
          ++ without their multiplicity. See also \spadfun{parts}.
        remove: (S,%,Integer) -> %
          ++ remove(x,ms,number) removes at most \spad{number} copies of
          ++ element x if \spad{number} is positive, all of them if
          ++ \spad{number} equals zero, and all but at most \spad{-number} if
          ++ \spad{number} is negative.
        remove: ( S -> Boolean ,%,Integer) -> %
          ++ remove(p,ms,number) removes at most \spad{number} copies of
          ++ elements x such that \spad{p(x)} is \spadfun{true}
          ++ if \spad{number} is positive, all of them if
          ++ \spad{number} equals zero, and all but at most \spad{-number} if
          ++ \spad{number} is negative.
        remove_!: (S,%,Integer) -> %
          ++ remove!(x,ms,number) removes destructively at most \spad{number}
          ++ copies of element x if \spad{number} is positive, all
          ++ of them if \spad{number} equals zero, and all but at most
          ++ \spad{-number} if \spad{number} is negative.
        remove_!: ( S -> Boolean ,%,Integer) -> %
          ++ remove!(p,ms,number) removes destructively at most \spad{number}
          ++ copies of elements x such that \spad{p(x)} is
          ++ \spadfun{true} if \spad{number} is positive, all of them if
          ++ \spad{number} equals zero, and all but at most \spad{-number} if
          ++ \spad{number} is negative.

=====================================================================
MultivariatePolynomial examples
=====================================================================

The domain constructor MultivariatePolynomial is similar to Polynomial
except that it specifies the variables to be used.  Polynomial are
available for MultivariatePolynomial.  The abbreviation for
MultivariatePolynomial is MPOLY.  The type expressions

  MultivariatePolynomial([x,y],Integer)
  MPOLY([x,y],INT)
```

```
refer to the domain of multivariate polynomials in the variables x and
y where the coefficients are restricted to be integers.  The first
variable specified is the main variable and the display of the polynomial
reflects this.

This polynomial appears with terms in descending powers of the variable x.

  m : MPOLY([x,y],INT) := (x^2 - x*y^3 +3*y)^2
     4     3 3     6       2     4      2
    x  - 2y x  + (y  + 6y)x  - 6y x + 9y
                     Type: MultivariatePolynomial([x,y],Integer)

It is easy to see a different variable ordering by doing a conversion.

  m :: MPOLY([y,x],INT)
     2 6       4     3 3     2     2     4
    x y  - 6x y  - 2x y  + 9y  + 6x y + x
                     Type: MultivariatePolynomial([y,x],Integer)

You can use other, unspecified variables, by using Polynomial in the
coefficient type of MPOLY.

  p : MPOLY([x,y],POLY INT)
                     Type: Void

Conversions can be used to re-express such polynomials in terms of
the other variables.  For example, you can first push all the
variables into a polynomial with integer coefficients.

  p :: POLY INT
    p
                     Type: Polynomial Integer

Now pull out the variables of interest.

  % :: MPOLY([a,b],POLY INT)
    p
                     Type: MultivariatePolynomial([a,b],Polynomial Integer)

Restriction:
  Axiom does not allow you to create types where MultivariatePolynomial
  is contained in the coefficient type of Polynomial. Therefore,
  MPOLY([x,y],POLY INT) is legal but POLY MPOLY([x,y],INT) is not.

Multivariate polynomials may be combined with univariate polynomials
to create types with special structures.

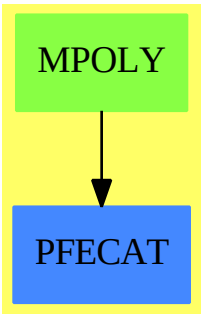
  q : UP(x, FRAC MPOLY([y,z],INT))
                          Type: Void
```

This is a polynomial in x whose coefficients are quotients of polynomials in y and z.

```
  q := (x^2 - x*(z+1)/y +2)^2
                              2    2
        4   - 2z - 2  3   4y  + z  + 2z + 1  2   - 4z - 4
   (7)  x  + -------- x  + ----------------- x  + -------- x + 4
                y                  2                 y
                                  y
 Type: UnivariatePolynomial(x,Fraction MultivariatePolynomial([y,z],Integer))
```

Use conversions for structural rearrangements. z does not appear in a denominator and so it can be made the main variable.

```
  q :: UP(z, FRAC MPOLY([x,y],INT))
    2           3     2            2 4       3      2      2            2
   x   2   - 2y x  + 2x  - 4y x     y x  - 2y x  + (4y  + 1)x  - 4y x + 4y
   -- z  + -------------------- z + ------------------------------------
    2               2                                 2
   y               y                                 y
 Type: UnivariatePolynomial(z,Fraction MultivariatePolynomial([x,y],Integer))
```



Or you can make a multivariate polynomial in x and z whose coefficients are fractions in polynomials in y.

```
  q :: MPOLY([x,z], FRAC UP(y,INT))
     4      2     2  3     1  2    2     4y  + 1  2      4     4
    x  + (- - z - -)x  + (-- z  + -- z + -------)x  + (- - z - -)x + 4
           y     y        2       2         2           y     y
                         y       y         y
 Type: MultivariatePolynomial([x,z],Fraction UnivariatePolynomial(y,Integer))
```

A conversion like q :: MPOLY([x,y], FRAC UP(z,INT)) is not possible in this example because y appears in the denominator of a fraction. As you can see, Axiom provides extraordinary flexibility in the manipulation and display of expressions via its conversion facility.

— domain MPOLY MultivariatePolynomial —

```
)abbrev domain MPOLY MultivariatePolynomial
++ Author: Dave Barton, Barry Trager
++ Description:
++ This type is the basic representation of sparse recursive multivariate
++ polynomials whose variables are from a user specified list of symbols.
++ The ordering is specified by the position of the variable in the list.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.

MultivariatePolynomial(vl:List Symbol, R:Ring)
   ==  SparseMultivariatePolynomial(--SparseUnivariatePolynomial,
          R, OrderedVariableList vl)

domain NSMP NewSparseMultivariatePolynomial

Based on the **PseudoRemainderSequence** package, the domain constructor **NewSparseMulitvariatePolynomial** extends the constructor **SparseMultivariatePolynomial**. It also provides some additional operations related to polynomial system solving by means of triangular sets.

====================================================================
None examples
====================================================================

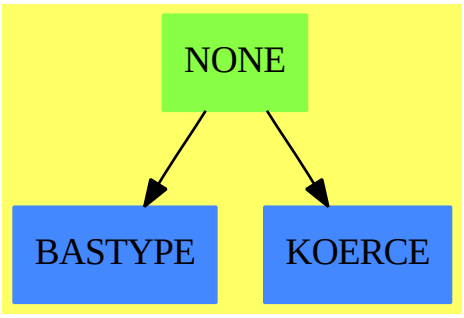
The None domain is not very useful for interactive work but it is
provided nevertheless for completeness of the Axiom type system.

Probably the only place you will ever see it is if you enter an
empty list with no type information.

  [ ]
    []
                        Type: List None

Such an empty list can be converted into an empty list of any other
type.

  [ ] :: List Float
    []
                        Type: List Float



If you wish to produce an empty list of a particular type directly,
such as List NonNegativeInteger, do it this way.

  [ ]$List(NonNegativeInteger)
    []
                        Type: List NonNegativeInteger

                              n
If F is a finite field with p  elements, then we may form the group
of all formal power series {t(1+a t+a t+...)} where u(0)=0 and
 ,                                1   2
u (0)=1 and $a is an element of F.
             i
The group operation is substitution (composition).
This is called the Nottingham Group.

The Nottingham Group is the projective limit of finite p-groups.
Every finite p-group can be embedded in the Nottingham Group.

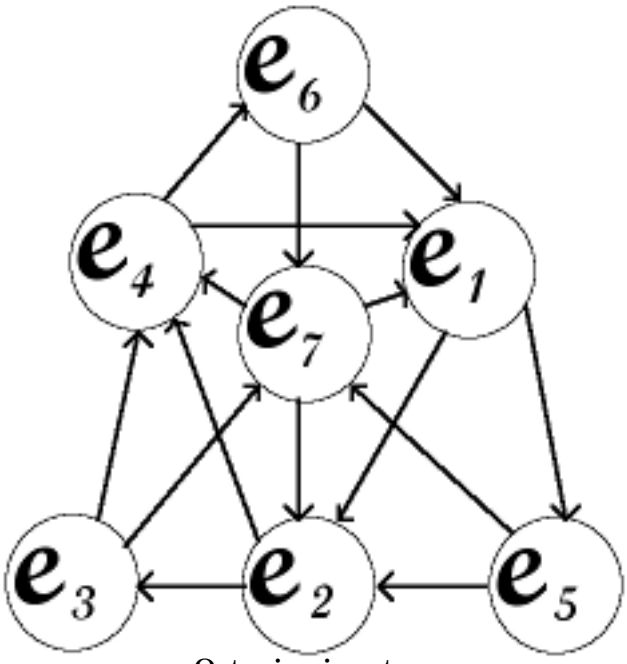
Chapter 16

Chapter O

domain OCT Octonion



The octonions have the following multiplication table:

1	i	j	k	E	I	J	K
i	-1	k	$-j$	I	$-E$	$-K$	J
j	$-k$	-1	i	J	K	$-E$	$-I$
k	j	$-i$	-1	K	$-J$	I	$-E$
E	$-I$	$-J$	$-K$	-1	i	j	k
I	E	$-K$	J	$-i$	-1	$-k$	j
J	K	E	$-I$	$-j$	k	-1	$-i$
K	$-J$	I	E	$-k$	$-j$	i	-1

There are 3 different kinds of associativity. An algebra is

- **power-associative** if the subalgebra generated by any one element is associative. That is, given any element e then $e * (e * e) = (e * e) * e$.
- **alternative** if the subalgebra generated by any two elements is associative That is, given any two elements, a and b then $a * (a * b) = (a * a) * b$ and $a * (b * a) = (a * b) * a$ and $b * (a * a) = (b * a) * a$.
- **associative** if the subalgebra generated by any three elements is associative. That is, given any three elements a, b, and c then $a * (b * c) = (a * b) * c$.

The Octonions are power-associative and alternative but not associative, since $I * (J * K) \neq (I * J) * K$.

=====================================================================
Octonion examples
=====================================================================

The Octonions, also called the Cayley-Dixon algebra, defined over a
commutative ring are an eight-dimensional non-associative algebra.
Their construction from quaternions is similar to the construction
of quaternions from complex numbers.

As Octonion creates an eight-dimensional algebra, you have to give
eight components to construct an octonion.

  oci1 := octon(1,2,3,4,5,6,7,8)
    1 + 2i + 3j + 4k + 5E + 6I + 7J + 8K
                              Type: Octonion Integer

  oci2 := octon(7,2,3,-4,5,6,-7,0)
    7 + 2i + 3j - 4k + 5E + 6I - 7J
                              Type: Octonion Integer

Or you can use two quaternions to create an octonion.

  oci3 := octon(quatern(-7,-12,3,-10), quatern(5,6,9,0))
    - 7 - 12i + 3j - 10k + 5E + 6I + 9J
                              Type: Octonion Integer

You can easily demonstrate the non-associativity of multiplication.

  (oci1 * oci2) * oci3 - oci1 * (oci2 * oci3)
    2696i - 2928j - 4072k + 16E - 1192I + 832J + 2616K
                              Type: Octonion Integer

As with the quaternions, we have a real part, the imaginary parts
i, j, k, and four additional imaginary parts E, I, J and K. These
parts correspond to the canonical basis (1,i,j,k,E,I,J,K).

For each basis element there is a component operation to extract the
coefficient of the basis element for a given octonion.
```

```
  [real oci1, imagi oci1, imagj oci1, imagk oci1, _
   imagE oci1, imagI oci1, imagJ oci1, imagK oci1]
    [1,2,3,4,5,6,7,8]
                              Type: List PositiveInteger
```

A basis with respect to the quaternions is given by (1,E). However, you might ask, what then are the commuting rules? To answer this, we create some generic elements.

We do this in Axiom by simply changing the ground ring from Integer to Polynomial Integer.

```
  q : Quaternion Polynomial Integer := quatern(q1, qi, qj, qk)
    q1 + qi i + qj j + qk k
                              Type: Quaternion Polynomial Integer

  E : Octonion Polynomial Integer:= octon(0,0,0,0,1,0,0,0)
    E
                              Type: Octonion Polynomial Integer
```

Note that quaternions are automatically converted to octonions in the obvious way.

```
  q * E
    q1 E + qi I + qj J + qk K
                              Type: Octonion Polynomial Integer

  E * q
    q1 E - qi I - qj J - qk K
                              Type: Octonion Polynomial Integer

  q * 1$(Octonion Polynomial Integer)
    q1 + qi i + qj j + qk k
                              Type: Octonion Polynomial Integer

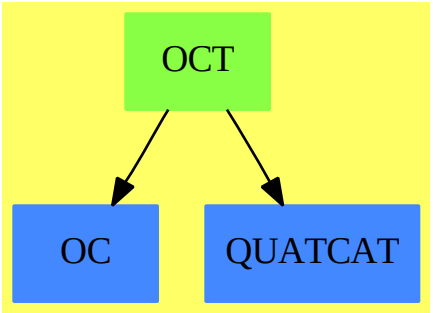
  1$(Octonion Polynomial Integer) * q
    q1 + qi i + qj j + qk k
                              Type: Octonion Polynomial Integer
```

Finally, we check that the norm, defined as the sum of the squares of the coefficients, is a multiplicative map.

```
  o : Octonion Polynomial Integer := octon(o1, oi, oj, ok, oE, oI, oJ, oK)
    o1 + oi i + oj j + ok k + oE E + oI I + oJ J + oK K
                              Type: Octonion Polynomial Integer

  norm o
      2     2     2     2     2     2     2     2
    ok  + oj  + oi  + oK  + oJ  + oI  + oE  + o1
                              Type: Polynomial Integer
```

```
  p : Octonion Polynomial Integer := octon(p1, pi, pj, pk, pE, pI, pJ, pK)
    p1 + pi i + pj j + pk k + pE E + pI I + pJ J + pK K
                              Type: Octonion Polynomial Integer



Since the result is 0, the norm is multiplicative.

  norm(o*p)-norm(p)*norm(o)
    0
                              Type: Polynomial Integer

=====================================================================
OneDimensionalArray examples
=====================================================================

The OneDimensionalArray domain is used for storing data in a
one-dimensional indexed data structure.  Such an array is a
homogeneous data structure in that all the entries of the array must
belong to the same Axiom domain.  Each array has a fixed length
specified by the user and arrays are not extensible.  The indexing of
one-dimensional arrays is one-based.  This means that the "first"
element of an array is given the index 1.

To create a one-dimensional array, apply the operation
oneDimensionalArray to a list.

  oneDimensionalArray [i**2 for i in 1..10]
    [1,4,9,16,25,36,49,64,81,100]
                    Type: OneDimensionalArray PositiveInteger

Another approach is to first create a, a one-dimensional array of 10
0's.  OneDimensionalArray has the convenient abbreviation ARRAY1.

  a : ARRAY1 INT := new(10,0)
    [0,0,0,0,0,0,0,0,0,0]
```

```
                    Type: OneDimensionalArray Integer

Set each i-th element to i, then display the result.

  for i in 1..10 repeat a.i := i; a
    [1,2,3,4,5,6,7,8,9,10]
                    Type: OneDimensionalArray Integer

Square each element by mapping the function i +-> i^2 onto each element.

  map!(i +-> i ** 2,a); a
    [1,4,9,16,25,36,49,64,81,100]
                    Type: OneDimensionalArray Integer

Reverse the elements in place.

  reverse! a
    [100,81,64,49,36,25,16,9,4,1]
                    Type: OneDimensionalArray Integer

Swap the 4th and 5th element.

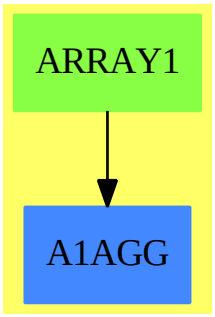
  swap!(a,4,5); a
    [100,81,64,36,49,25,16,9,4,1]
                    Type: OneDimensionalArray Integer

Sort the elements in place.

  sort! a
    [1,4,9,16,25,36,49,64,81,100]
                    Type: OneDimensionalArray Integer

Create a new one-dimensional array b containing the last 5 elements of a.

  b := a(6..10)
    [36,49,64,81,100]
                    Type: OneDimensionalArray Integer



Replace the first 5 elements of a with those of b.

  copyInto!(a,b,1)
    [36,49,64,81,100,36,49,64,81,100]
                    Type: OneDimensionalArray Integer

=====================================================================
Operator examples
=====================================================================

Given any ring R, the ring of the Integer-linear operators over R is
called Operator(R).  To create an operator over R, first create a
basic operator using the operation operator, and then convert it to
Operator(R) for the R you want.

We choose R to be the two by two matrices over the integers.

  R := SQMATRIX(2, INT)
    SquareMatrix(2,Integer)
                             Type: Domain

Create the operator tilde on R.

  t := operator("tilde") :: OP(R)
    tilde
                             Type: Operator SquareMatrix(2,Integer)

Since Operator is unexposed we must either package-call operations
from it, or expose it explicitly.  For convenience we will do the latter.

Expose Operator.

  )set expose add constructor Operator

To attach an evaluation function (from R to R) to an operator over R,
use evaluate(op, f) where op is an operator over R and f is a function
R -> R.  This needs to be done only once when the operator is defined.
Note that f must be Integer-linear (that is, f(ax+y) = a f(x) + f(y)
for any integer a, and any x and y in R).
```

```
We now attach the transpose map to the above operator t.

  evaluate(t, m +-> transpose m)
    tilde
                        Type: Operator SquareMatrix(2,Integer)

Operators can be manipulated formally as in any ring: + is the
pointwise addition and * is composition.  Any element x of R can be
converted to an operator op(x) over R, and the evaluation function of
op(x) is left-multiplication by x.

Multiplying on the left by this matrix swaps the two rows.

  s : R := matrix [ [0, 1], [1, 0] ]
        +0  1+
        |    |
        +1  0+
                        Type: SquareMatrix(2,Integer)

Can you guess what is the action of the following operator?

  rho := t * s
             +0  1+
        tilde|    |
             +1  0+
                        Type: Operator SquareMatrix(2,Integer)

Hint: applying rho four times gives the identity, so rho^4-1 should
return 0 when applied to any two by two matrix.

  z := rho**4 - 1
                  +0  1+     +0  1+     +0  1+     +0  1+
        - 1 + tilde|    |tilde|    |tilde|    |tilde|    |
                  +1  0+     +1  0+     +1  0+     +1  0+
                      Type: Operator SquareMatrix(2,Integer)

Now check with this matrix.

  m:R := matrix [ [1, 2], [3, 4] ]
        +1  2+
        |    |
        +3  4+
                        Type: SquareMatrix(2,Integer)

  z m
        +0  0+
        |    |
        +0  0+
                        Type: SquareMatrix(2,Integer)
```

```
As you have probably guessed by now, rho acts on matrices by rotating
the elements clockwise.

  rho m
        +3  1+
        |    |
        +4  2+
                        Type: SquareMatrix(2,Integer)

  rho rho m
         +4  3+
         |    |
         +2  1+
                        Type: SquareMatrix(2,Integer)

  (rho^3) m
         +2  4+
         |    |
         +1  3+
                        Type: SquareMatrix(2,Integer)

Do the swapping of rows and transposition commute?  We can check by
computing their bracket.

  b := t * s - s * t
           +0  1+             +0  1+
         - |    |tilde + tilde|    |
           +1  0+             +1  0+
                        Type: Operator SquareMatrix(2,Integer)

Now apply it to m.

  b m
         +1  - 3+
         |      |
         +3  - 1+
                        Type: SquareMatrix(2,Integer)

Next we demonstrate how to define a differential operator on a polynomial ring.

This is the recursive definition of the n-th Legendre polynomial.

  L n ==
    n = 0 => 1
    n = 1 => x
    (2*n-1)/n * x * L(n-1) - (n-1)/n * L(n-2)
                         Type: Void

Create the differential operator d/dx on polynomials in x over the
```

rational numbers.

```
  dx := operator("D") :: OP(POLY FRAC INT)
     D
                        Type: Operator Polynomial Fraction Integer
```

Now attach the map to it.

```
  evaluate(dx, p +-> D(p, 'x))
    D
                        Type: Operator Polynomial Fraction Integer
```

This is the differential equation satisfied by the n-th Legendre polynomial.

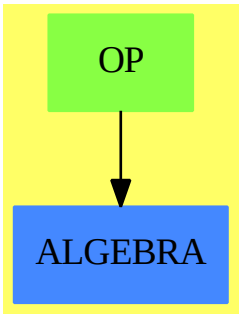
```
  E n == (1 - x**2) * dx**2 - 2 * x * dx + n*(n+1)
                        Type: Void
```

Now we verify this for n = 15. Here is the polynomial.

```
  L 15
     9694845  15   35102025  13   50702925  11   37182145  9   14549535  7
     ------- x   - -------- x   + -------- x   - -------- x  + -------- x
       2048          2048           2048           2048          2048
   +
       2909907  5   255255  3   6435
     - ------- x  + ------ x  - ---- x
         2048        2048       2048
                        Type: Polynomial Fraction Integer
```

Here is the operator.

```
  E 15
    240 - 2x D - (x  - 1)D
                        Type: Operator Polynomial Fraction Integer
```



Here is the evaluation.

```
  (E 15)(L 15)
    0
                        Type: Polynomial Fraction Integer
```

```
==========================================================================
OrderedFreeMonoid examples
==========================================================================

The free monoid on a set S is the monoid of finite products of
the form reduce(*,[si ** ni]) where the si's are in S, and the ni's
are non-negative integers. The multiplication is not commutative.
For two elements x and y the relation x < y holds if either
length(x) < length(y) holds or if these lengths are equal and if
x is smaller than y w.r.t. the lexicographical ordering induced by S.
This domain inherits implementation from FreeMonoid.

m1:=(x*y*y*z)$OFMONOID(Symbol)

m2:=(x*y)$OFMONOID(Symbol)

lquo(m1,m2)

m3:=(y*y)$OFMONOID(Symbol)

div(m1,m2)

div(m1,m3)

m4:=(y^3)$OFMONOID(Symbol)

div(m1,m4)

Build the non-commutative algebra h=k[x,y] and then make computations
in h using some predefined rules for x and y. For example, giving

   x*y*x=y*x*y
   x*x=a*x+b
   y*y=a*y+b

where a dn b are generic elements of k.

Then reduce the polynomials in x and y according to the previous rules.
That is, given

   (x+y)^2   ( = x^2+x*y+y*x+y^2)

should reduce to
```

```
   a*(x+y)+2*b+x*y+y*x
```

We can reduce the clutter of the work by defining macros for the types
of the domains we need to create. So first we create those macros.

We create generic elements of k. First we define a macro for the domain of
ordered variables (OVAR is OrderedVariableList)

```
  C ==> OVAR [a,b]
```

Next we define a macro for the commutative field domain k = Q[a,b]
where Q is Fraction(Integer) and SMP is SparseMultivariatePolynomials

```
  K ==> SMP(FRAC INT,C)
```

Now we need some non-commutative variables so we create a macro for that.

```
  V ==> OVAR [x,y]
```

And now we need to define the non-commuative algebra k=k[x,y].
We use the domain XDistributedPolynomial (XDPOLY) as a macro.

```
  H ==> XDPOLY(V,K)
```

The non-commutative variables are in an Ordered Free Monoid

```
  M ==> OFMONOID V
```

We have three rules to apply. So we create a function that examines one
term. Substitution rules are applied to words from the monoid over the
variables and retun polynomials. If any rule matches we construct the
substitution, create a new monomial term and return it.

```
  subs(w:M):H ==
    -- x*y*x = y*x*y
    n1:=lquo(w,(x::V*y::V*x::V)$M)$M
    n1 case "failed" => monom(w,1)$H
        -- x*x = a*x+b
      n2:=lquo(w,(x::V^2)$M)$M
      n2 case "failed" => monom(w,1)$H
        -- y*y = a*y+b
        n3:lquo(w,(y::V^2)$M)$M
        n3 case "failed" => monom(w,1)$H
        monom(n3,1)$H * (a::K*y::V+b::K)$M * monom(n3,1)$H
      monom(n2,1)$H * (a::K*x::V+b::K)$H * monom(n2,1)$H
    monom(n1,1)$H * (y::V*x::V*y::V)$H * monom(n1,1)$H
```

We apply these rules to a term, remembering the coefficient

```
  newterm(x:Record(k:M,c:K)):H == x.c*subs(x,k)
```

And now we create a function to reconstruct the polynomial term by term.

```
  newpoly(t:H):H == reduce(+,map(newterm,listOfTerms(t)))
```

For example,

```
  p1:(x::V+y::V)$H^2

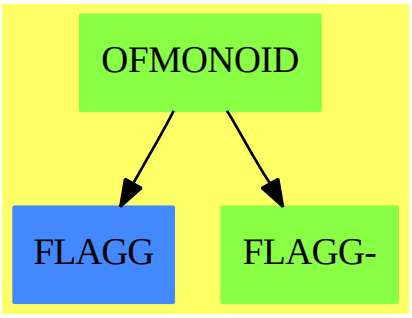
  newpoly(p1)

  p2:=(x::V+y::V)$H^3

  pNew:=newpoly(p2)
```

But the rules should be applied more than once so we create a function
to iterate the rules until nothing changes.

```
  reduce(p:H):H ==
    p2 := newpoly(p)
    p3 := newpoly(p2)
    while p3 ~= p2 repeat
      p2 := p3
      p3 := newpoly(p2)
    p3
```



And we can see it work

```
  reduce(p2)
```

=====================================================================
OrderedVariableList examples
=====================================================================

The domain OrderedVariableList provides symbols which are restricted
to a particular list and have a definite ordering. Those two features
are specified by a List Symbol object that is the argument to the
domain.

This is a sample ordering of three symbols.

  ls:List Symbol:=['x,'a,'z]
    [x,a,z]
                                Type: List Symbol

Let's build the domain

  Z:=OVAR ls
    OrderedVariableList [x,a,z]
                                Type: Domain

How many variables does it have?

  size()$Z
```

```
    3
                                    Type: NonNegativeInteger

They are (in the imposed order)

  lv:=[index(i::PI)$Z for i in 1..size()$Z]
    [x,a,z]
                                    Type: List OrderedVariableList [x,a,z]

Check that the ordering is right

  sorted?(>,lv)
    true
                                    Type: Boolean

=====================================================================
OrderlyDifferentialPolynomial examples
=====================================================================
```

Many systems of differential equations may be transformed to equivalent systems of ordinary differential equations where the equations are expressed polynomially in terms of the unknown functions. In Axiom, the domain constructors OrderlyDifferentialPolynomial (abbreviated ODPOL) and SequentialDifferentialPolynomial (abbreviation SDPOL) implement two domains of ordinary differential polynomials over any differential ring. In the simplest case, this differential ring is usually either the ring of integers, or the field of rational numbers. However, Axiom can handle ordinary differential polynomials over a field of rational functions in a single indeterminate.

The two domains ODPOL and SDPOL are almost identical, the only difference being the choice of a different ranking, which is an ordering of the derivatives of the indeterminates. The first domain uses an orderly ranking, that is, derivatives of higher order are ranked higher, and derivatives of the same order are ranked alphabetically. The second domain uses a sequential ranking, where derivatives are ordered first alphabetically by the differential indeterminates, and then by order. A more general domain constructor, DifferentialSparseMultivariatePolynomial (abbreviation DSMP) allows both a user-provided list of differential indeterminates as well as a user-defined ranking. We shall illustrate ODPOL(FRAC INT), which constructs a domain of ordinary differential polynomials in an arbitrary number of differential indeterminates with rational numbers as coefficients.

```
  dpol:= ODPOL(FRAC INT)
    OrderlyDifferentialPolynomial Fraction Integer
                            Type: Domain
```

A differential indeterminate w may be viewed as an infinite sequence of algebraic indeterminates, which are the derivatives of w. To facilitate referencing these, Axiom provides the operation makeVariable to convert an element of type Symbol to a map from the natural numbers to the differential polynomial ring.

```
  w := makeVariable('w)$dpol
    theMap(DPOLCAT-;makeVariable;AM;17!0,0)
 Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)

  z := makeVariable('z)$dpol
    theMap(DPOLCAT-;makeVariable;AM;17!0,0)
 Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

The fifth derivative of w can be obtained by applying the map w to the number 5. Note that the order of differentiation is given as a subscript (except when the order is 0).

```
  w.5
    w
     5
```

```
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

```
w 0
  w
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

The first five derivatives of z can be generated by a list.

```
[z.i for i in 1..5]
  [z ,z ,z ,z ,z ]
    1  2  3  4  5
                  Type: List OrderlyDifferentialPolynomial Fraction Integer
```

The usual arithmetic can be used to form a differential polynomial from the derivatives.

```
f:= w.4 - w.1 * w.1 * z.3
         2
  w  - w  z
   4    1  3
                  Type: OrderlyDifferentialPolynomial Fraction Integer
```

```
g:=(z.1)**3 * (z.2)**2 - w.2
    3  2
  z  z   - w
   1  2     2
                  Type: OrderlyDifferentialPolynomial Fraction Integer
```

The operation D computes the derivative of any differential polynomial.

```
D(f)
         2
  w  - w  z  - 2w w z
   5    1  4     1 2 3
                  Type: OrderlyDifferentialPolynomial Fraction Integer
```

The same operation can compute higher derivatives, like the fourth derivative.

```
D(f,4)
          2                                2
   w  - w  z  - 8w w z  + (- 12w w  - 12w  )z  - 2w z w
    8    1  7     1 2 6         1 3      2   5     1 3 5
 +
                                      2
   (- 8w w  - 24w w )z  - 8w z w  - 6w  z
        1 4      2 3  4     2 3 4     3  3
                       Type: OrderlyDifferentialPolynomial Fraction Integer
```

The operation makeVariable creates a map to facilitate referencing the derivatives of f, similar to the map w.

```
  df:=makeVariable(f)$dpol
    theMap(DPOLCAT-;makeVariable;AM;17!0,0)
 Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

The fourth derivative of f may be referenced easily.

```
  df.4
           2                                  2
     w  - w  z  - 8w w z  + (- 12w w  - 12w  )z  - 2w z w
      8    1  7     1 2 6         1 3      2   5     1 3 5
   +
                                        2
     (- 8w w  - 24w w )z  - 8w z w  - 6w  z
          1 4      2 3  4     2 3 4     3  3
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

The operation order returns the order of a differential polynomial,
or the order in a specified differential indeterminate.

```
  order(g)
    2
                    Type: PositiveInteger

  order(g, 'w)
    2
                    Type: PositiveInteger
```

The operation differentialVariables returns a list of differential
indeterminates occurring in a differential polynomial.

```
  differentialVariables(g)
    [z,w]
                    Type: List Symbol
```

The operation degree returns the degree, or the degree in the differential
indeterminate specified.

```
  degree(g)
       2  3
     z  z
      2  1
                    Type: IndexedExponents OrderlyDifferentialVariable Symbol

  degree(g, 'w)
    1
                    Type: PositiveInteger
```

The operation weights returns a list of weights of differential monomials
appearing in differential polynomial, or a list of weights in a specified

differential indeterminate.

```
  weights(g)
    [7,2]
                    Type: List NonNegativeInteger

  weights(g,'w)
    [2]
                    Type: List NonNegativeInteger
```

The operation weight returns the maximum weight of all differential monomials appearing in the differential polynomial.

```
  weight(g)
    7
                    Type: PositiveInteger
```

A differential polynomial is isobaric if the weights of all differential monomials appearing in it are equal.

```
  isobaric?(g)
    false
                    Type: Boolean
```

To substitute differentially, use eval. Note that we must coerce 'w to Symbol, since in ODPOL, differential indeterminates belong to the domain Symbol. Compare this result to the next, which substitutes algebraically (no substitution is done since w.0 does not appear in g).

```
  eval(g,['w::Symbol],[f])
              2                              2        3  2
    - w  + w  z  + 4w w z  + (2w w  + 2w  )z  + z  z
       6    1  5     1 2 4      1 3     2   3    1  2
                    Type: OrderlyDifferentialPolynomial Fraction Integer

  eval(g,variables(w.0),[f])
       3  2
    z  z   - w
     1  2     2
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

Since OrderlyDifferentialPolynomial belongs to PolynomialCategory, all the operations defined in the latter category, or in packages for the latter category, are available.

```
  monomials(g)
       3  2
    [z  z  ,- w ]
      1  2     2
                    Type: List OrderlyDifferentialPolynomial Fraction Integer
```

```
variables(g)
  [z ,w ,z ]
    2  2  1
                    Type: List OrderlyDifferentialVariable Symbol

gcd(f,g)
  1
                    Type: OrderlyDifferentialPolynomial Fraction Integer

groebner([f,g])
           2     3  2
   [w  - w  z ,z  z   - w ]
     4    1  3  1  2     2
                    Type: List OrderlyDifferentialPolynomial Fraction Integer
```

The next three operations are essential for elimination procedures in differential polynomial rings. The operation leader returns the leader of a differential polynomial, which is the highest ranked derivative of the differential indeterminates that occurs.

```
lg:=leader(g)
   z
    2
                    Type: OrderlyDifferentialVariable Symbol
```

The operation separant returns the separant of a differential polynomial, which is the partial derivative with respect to the leader.

```
sg:=separant(g)
     3
  2z  z
    1  2
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

The operation initial returns the initial, which is the leading coefficient when the given differential polynomial is expressed as a polynomial in the leader.

```
ig:=initial(g)
    3
  z
   1
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

Using these three operations, it is possible to reduce f modulo the differential ideal generated by g. The general scheme is to first reduce the order, then reduce the degree in the leader. First, eliminate z.3 using the derivative of g.

```
  g1 := D g
       3               2  3
    2z  z z  - w  + 3z  z
      1  2 3    3     1  2
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

Find its leader.

```
  lg1:= leader g1
    z
     3
                    Type: OrderlyDifferentialVariable Symbol
```

Differentiate f partially with respect to this leader.

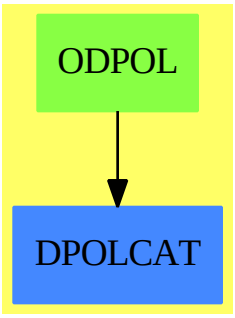
```
  pdf:=D(f, lg1)
        2
    - w
       1
                    Type: OrderlyDifferentialPolynomial Fraction Integer
```

Compute the partial remainder of f with respect to g.

```
  prf:=sg * f- pdf * g1
       3         2        2  2  3
    2z  z w  - w  w  + 3w  z  z
      1  2 4    1  3     1  1  2
                     Type: OrderlyDifferentialPolynomial Fraction Integer
```

Note that high powers of lg still appear in prf. Compute the leading coefficient of prf as a polynomial in the leader of g.

```
  lcf:=leadingCoefficient univariate(prf, lg)
       2  2
    3w  z
      1  1
                     Type: OrderlyDifferentialPolynomial Fraction Integer
```



Finally, continue eliminating the high powers of lg appearing in prf to obtain the (pseudo) remainder of f modulo g and its derivatives.

```
  ig * prf - lcf * g * lg
       6         2  3        2  2
    2z  z w  - w  z  w  + 3w  z  w z
      1  2 4    1  1  3     1  1  2 2
                     Type: OrderlyDifferentialPolynomial Fraction Integer
```

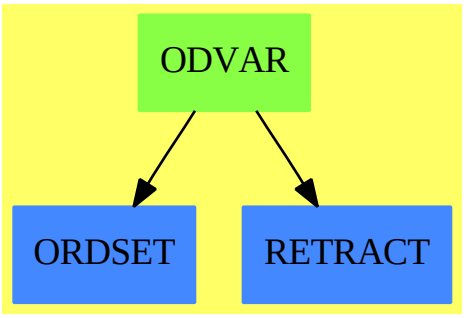
=====================================================================
OrderlyDifferentialVariable examples
=====================================================================



OrderlyDifferentialVariable adds a commonly used orderly ranking to
the set of derivatives of an ordered list of differential
indeterminates.  An orderly ranking is a ranking < of the derivatives
with the property that for two derivatives u and v, u < v if the
order of u is less than that of v.

This domain belongs to DifferentialVariableCategory. It defines
weight to be just order, and it defines an orderly ranking < on
derivatives u via the lexicographic order on the pair
(order(u), variable(u)).

)abbrev domain OUTFORM OutputForm
++ Author: SMW March/88
++ Description:
++ This domain is used to create and manipulate mathematical expressions
++ for output.  It is intended to provide an insulating layer between
++ the expression rendering software (e.g.FORTRAN, TeX, or Script) and
++ the output coercions in the various domains.

OutputForm(): SetCategory with
        --% Printing
        print  : $ -> Void
          ++ print(u) prints the form u.
        message: String -> $
          ++ message(s) creates an form with no string quotes
          ++ from string s.
        messagePrint: String -> Void
          ++ messagePrint(s) prints s without string quotes. Note:
          ++ \spad{messagePrint(s)} is equivalent to \spad{print message(s)}.
        --% Creation of atomic forms
        outputForm: Integer -> $
          ++ outputForm(n) creates an form for integer n.
        outputForm: Symbol  -> $
          ++ outputForm(s) creates an form for symbol s.
        outputForm: String  -> $
          ++ outputForm(s) creates an form for string s.
        outputForm: DoubleFloat  -> $
          ++ outputForm(sf) creates an form for small float sf.
        empty   : () -> $
          ++ empty() creates an empty form.
```

```
--% Sizings
width: $ -> Integer
  ++ width(f) returns the width of form f (an integer).
height: $ -> Integer
  ++ height(f) returns the height of form f (an integer).
width: -> Integer
  ++ width() returns the width of the display area (an integer).
height: -> Integer
  ++ height() returns the height of the display area (an integer).
subHeight: $ -> Integer
  ++ subHeight(f) returns the height of form f below the base line.
superHeight: $ -> Integer
  ++ superHeight(f) returns the height of form f above the base line.
 --% Space manipulations
hspace: Integer -> $  ++ hspace(n) creates white space of width n.
vspace: Integer -> $  ++ vspace(n) creates white space of height n.
rspace: (Integer,Integer) -> $
  ++ rspace(n,m) creates rectangular white space, n wide by m high.
--% Area adjustments
left: ($,Integer) -> $
  ++ left(f,n) left-justifies form f within space of width n.
right: ($,Integer) -> $
  ++ right(f,n) right-justifies form f within space of width n.
center: ($,Integer) -> $
  ++ center(f,n) centers form f within space of width n.
left: $ -> $
  ++ left(f) left-justifies form f in total space.
right: $ -> $
  ++ right(f) right-justifies form f in total space.
center:   $ -> $
  ++ center(f) centers form f in total space.

--% Area manipulations
hconcat:  ($,$) -> $
  ++ hconcat(f,g) horizontally concatenate forms f and g.
vconcat:  ($,$) -> $
  ++ vconcat(f,g) vertically concatenates forms f and g.
hconcat:  List $ -> $
  ++ hconcat(u) horizontally concatenates all forms in list u.
vconcat:  List $ -> $
  ++ vconcat(u) vertically concatenates all forms in list u.

--% Application formers
prefix:  ($, List $) -> $
  ++ prefix(f,l) creates a form depicting the n-ary prefix
  ++ application of f to a tuple of arguments given by list l.
infix:   ($, List $) -> $
  ++ infix(f,l) creates a form depicting the n-ary application
  ++ of infix operation f to a tuple of arguments l.
infix:   ($, $, $) -> $
```

```
  ++ infix(op, a, b) creates a form which prints as: a op b.
postfix: ($, $)    -> $
  ++ postfix(op, a)  creates a form which prints as: a op.
infix?: $ -> Boolean
  ++ infix?(op) returns true if op is an infix operator,
  ++ and false otherwise.
elt:     ($, List $) -> $
  ++ elt(op,l) creates a form for application of op
  ++ to list of arguments l.

--% Special forms
string:  $ -> $
  ++ string(f) creates f with string quotes.
label:   ($, $) -> $
  ++ label(n,f) gives form f an equation label n.
box:     $ -> $
  ++ box(f) encloses f in a box.
matrix:  List List $ -> $
  ++ matrix(llf) makes llf (a list of lists of forms) into
  ++ a form which displays as a matrix.
zag:     ($, $) -> $
  ++ zag(f,g) creates a form for the continued fraction form for f over g.
root:    $ -> $
  ++ root(f) creates a form for the square root of form f.
root:    ($, $) -> $
  ++ root(f,n) creates a form for the nth root of form f.
over:    ($, $) -> $
  ++ over(f,g) creates a form for the vertical fraction of f over g.
slash:   ($, $) -> $
  ++ slash(f,g) creates a form for the horizontal fraction of f over g.
assign:  ($, $) -> $
  ++ assign(f,g) creates a form for the assignment \spad{f := g}.
rarrow:  ($, $) -> $
  ++ rarrow(f,g) creates a form for the mapping \spad{f -> g}.
differentiate: ($, NonNegativeInteger) -> $
  ++ differentiate(f,n) creates a form for the nth derivative of f,
  ++ e.g. \spad{f'}, \spad{f''}, \spad{f'''},
  ++ "f super \spad{iv}".
binomial: ($, $) -> $
  ++ binomial(n,m) creates a form for the binomial coefficient of n and m.

--% Scripts
sub:     ($, $) -> $
  ++ sub(f,n) creates a form for f subscripted by n.
super:   ($, $) -> $
  ++ super(f,n) creates a form for f superscripted by n.
presub:  ($, $) -> $
  ++ presub(f,n) creates a form for f presubscripted by n.
presuper:($, $) -> $
  ++ presuper(f,n) creates a form for f presuperscripted by n.
```

```
scripts: ($, List $) -> $
    ++ \spad{scripts(f, [sub, super, presuper, presub])}
    ++  creates a form for f with scripts on all 4 corners.
supersub:($, List $) -> $
    ++ supersub(a,[sub1,super1,sub2,super2,...])
    ++ creates a form with each subscript aligned
    ++ under each superscript.

--% Diacritical marks
quote:   $ -> $
  ++ quote(f) creates the form f with a prefix quote.
dot:     $ -> $
  ++ dot(f) creates the form with a one dot overhead.
dot:     ($, NonNegativeInteger) -> $
  ++ dot(f,n) creates the form f with n dots overhead.
prime:   $ -> $
  ++ prime(f) creates the form f followed by a suffix prime (single quote).
prime:   ($, NonNegativeInteger) -> $
  ++ prime(f,n) creates the form f followed by n primes.
overbar: $ -> $
  ++ overbar(f) creates the form f with an overbar.
overlabel: ($, $) -> $
  ++ overlabel(x,f) creates the form f with "x overbar" over the top.

--% Plexes
sum:     ($)       -> $
  ++ sum(expr) creates the form prefixing expr by a capital sigma.
sum:     ($, $)    -> $
  ++ sum(expr,lowerlimit) creates the form prefixing expr by
  ++ a capital sigma with a lowerlimit.
sum:     ($, $, $) -> $
  ++ sum(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ a capital sigma with both a lowerlimit and upperlimit.
prod:    ($)       -> $
  ++ prod(expr) creates the form prefixing expr by a capital pi.
prod:    ($, $)    -> $
  ++ prod(expr,lowerlimit) creates the form prefixing expr by
  ++ a capital pi with a lowerlimit.
prod:    ($, $, $) -> $
  ++ prod(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ a capital pi with both a lowerlimit and upperlimit.
int:     ($)       -> $
  ++ int(expr) creates the form prefixing expr with an integral sign.
int:     ($, $)    -> $
  ++ int(expr,lowerlimit) creates the form prefixing expr by an
  ++ integral sign with a lowerlimit.
int:     ($, $, $) -> $
  ++ int(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ an integral sign with both a lowerlimit and upperlimit.
```

```
--% Matchfix forms
brace:   $ -> $
  ++ brace(f) creates the form enclosing f in braces (curly brackets).
brace:   List $ -> $
  ++ brace(lf) creates the form separating the elements of lf
  ++ by commas and encloses the result in curly brackets.
bracket: $ -> $
  ++ bracket(f) creates the form enclosing f in square brackets.
bracket: List $ -> $
  ++ bracket(lf) creates the form separating the elements of lf
  ++ by commas and encloses the result in square brackets.
paren:   $ -> $
  ++ paren(f) creates the form enclosing f in parentheses.
paren:   List $ -> $
  ++ paren(lf) creates the form separating the elements of lf
  ++ by commas and encloses the result in parentheses.

--% Separators for aggregates
pile:     List $ -> $
  ++ pile(l) creates the form consisting of the elements of l which
  ++ displays as a pile, i.e. the elements begin on a new line and
  ++ are indented right to the same margin.

commaSeparate: List $ -> $
  ++ commaSeparate(l) creates the form separating the elements of l
  ++ by commas.
semicolonSeparate:  List $ -> $
  ++ semicolonSeparate(l) creates the form separating the elements of l
  ++ by semicolons.
blankSeparate: List $ -> $
  ++ blankSeparate(l) creates the form separating the elements of l
  ++ by blanks.
--% Specific applications
"=":     ($, $) -> $
  ++ f = g creates the equivalent infix form.
"^=":    ($, $) -> $
  ++ f ^= g creates the equivalent infix form.
"<":     ($, $) -> $
  ++ f < g creates the equivalent infix form.
">":     ($, $) -> $
  ++ f > g creates the equivalent infix form.
"<=":    ($, $) -> $
  ++ f <= g creates the equivalent infix form.
">=":    ($, $) -> $
  ++ f >= g creates the equivalent infix form.
"+":     ($, $) -> $
  ++ f + g creates the equivalent infix form.
"-":     ($, $) -> $
  ++ f - g creates the equivalent infix form.
"-":     ($)    -> $
```

```
      ++ - f creates the equivalent prefix form.
    "*":     ($, $) -> $
      ++ f * g creates the equivalent infix form.
    "/":     ($, $) -> $
      ++ f / g creates the equivalent infix form.
    "**":    ($, $) -> $
      ++ f ** g creates the equivalent infix form.
    "div":   ($, $) -> $
      ++ f div g creates the equivalent infix form.
    "rem":   ($, $) -> $
      ++ f rem g creates the equivalent infix form.
    "quo":   ($, $) -> $
      ++ f quo g creates the equivalent infix form.
    "exquo": ($, $) -> $
      ++ exquo(f,g) creates the equivalent infix form.
    "and":   ($, $) -> $
      ++ f and g creates the equivalent infix form.
    "or":    ($, $) -> $
      ++ f or g creates the equivalent infix form.
    "not":   ($)    -> $
      ++ not f creates the equivalent prefix form.
    SEGMENT: ($,$)  -> $
      ++ SEGMENT(x,y) creates the infix form: \spad{x..y}.
    SEGMENT: ($)    -> $
      ++ SEGMENT(x) creates the prefix form: \spad{x..}.

— domain PADICRC PAdicRationalConstructor —

```
)abbrev domain PADICRC PAdicRationalConstructor
++ Author: Clifton J. Williamson
++ Date Created: 10 May 1990
++ Date Last Updated: 10 May 1990
++ Description:
++ This is the category of stream-based representations of Qp.

PAdicRationalConstructor(p,PADIC): Exports == Implementation where
  p     :   Integer
  PADIC :   PAdicIntegerCategory p
  CF    ==> ContinuedFraction
  I     ==> Integer
  NNI   ==> NonNegativeInteger
  OUT   ==> OutputForm
  L     ==> List
  RN    ==> Fraction Integer
  ST    ==> Stream
```

```
  Exports ==> QuotientFieldCategory(PADIC) with
    approximate: (%,I) -> RN
      ++ \spad{approximate(x,n)} returns a rational number y such that
      ++ \spad{y = x (mod p^n)}.
    continuedFraction: % -> CF RN
      ++ \spad{continuedFraction(x)} converts the p-adic rational number x
      ++ to a continued fraction.
    removeZeroes: % -> %
      ++ \spad{removeZeroes(x)} removes leading zeroes from the
      ++ representation of the p-adic rational \spad{x}.
      ++ A p-adic rational is represented by (1) an exponent and
      ++ (2) a p-adic integer which may have leading zero digits.
      ++ When the p-adic integer has a leading zero digit, a 'leading zero'
      ++ is removed from the p-adic rational as follows:
      ++ the number is rewritten by increasing the exponent by 1 and
      ++ dividing the p-adic integer by p.
      ++ Note: \spad{removeZeroes(f)} removes all leading zeroes from f.
    removeZeroes: (I,%) -> %
      ++ \spad{removeZeroes(n,x)} removes up to n leading zeroes from
      ++ the p-adic rational \spad{x}.

========================================================================
PartialFraction examples
========================================================================

A partial fraction is a decomposition of a quotient into a sum of
quotients where the denominators of the summands are powers of
primes. Most people first encounter partial fractions when they are
learning integral calculus.  For a technical discussion of partial
fractions, see, for example, Lang's Algebra. For example, the rational
number 1/6 is decomposed into 1/2-1/3.  You can compute partial
fractions of quotients of objects from domains belonging to the
category EuclideanDomain.  For example, Integer, Complex Integer, and
UnivariatePolynomial(x, Fraction Integer) all belong to EuclideanDomain.
In the examples following, we demonstrate how to decompose quotients of
each of these kinds of object into partial fractions.

It is necessary that we know how to factor the denominator when we
want to compute a partial fraction.  Although the interpreter can
often do this automatically, it may be necessary for you to include a
call to factor.  In these examples, it is not necessary to factor the
denominators explicitly.

The main operation for computing partial fractions is called partialFraction
and we use this to compute a decomposition of 1/10!. The first argument to
partialFraction is the numerator of the quotient and the second argument is
the factored denominator.

  partialFraction(1,factorial 10)
    159   23   12   1
    --- - -- - -- + -
```

```
     8    4    2   7
    2    3    5
                          Type: PartialFraction Integer
```

Since the denominators are powers of primes, it may be possible to expand the numerators further with respect to those primes. Use the operation padicFraction to do this.

```
  f := padicFraction(%)
    1    1    1    1    1    1    2    1    2   2    2   1
    - + -- + -- + -- + -- + -- + -- - -- - -- - -- - - - -- + -
    2    4    5    6    7    8    2    3    4   5    2   7
        2    2    2    2    2    3    3    3        5
                          Type: PartialFraction Integer
```

The operation compactFraction returns an expanded fraction into the usual form. The compacted version is used internally for computational efficiency.

```
  compactFraction(f)
    159   23   12   1
    --- - -- - -- + -
      8    4    2   7
     2    3    5
                          Type: PartialFraction Integer
```

You can add, subtract, multiply and divide partial fractions. In addition, you can extract the parts of the decomposition. numberOfFractionalTerms computes the number of terms in the fractional part. This does not include the whole part of the fraction, which you get by calling wholePart. In this example, the whole part is just 0.

```
  numberOfFractionalTerms(f)
    12
                          Type: PositiveInteger
```

The operation nthFractionalTerm returns the individual terms in the decomposition. Notice that the object returned is a partial fraction itself. firstNumer and firstDenom extract the numerator and denominator of the first term of the fraction.

```
  nthFractionalTerm(f,3)
      1
     --
      5
     2
                          Type: PartialFraction Integer
```

Given two gaussian integers, you can decompose their quotient into a partial fraction.

```
partialFraction(1,- 13 + 14 * %i)
       1         4
  - ------- + -------
    1 + 2%i   3 + 8%i
                        Type: PartialFraction Complex Integer
```

To convert back to a quotient, simply use a conversion.

```
% :: Fraction Complex Integer
       %i
  - ---------
    14 + 13%i
                        Type: Fraction Complex Integer
```

To conclude this section, we compute the decomposition of

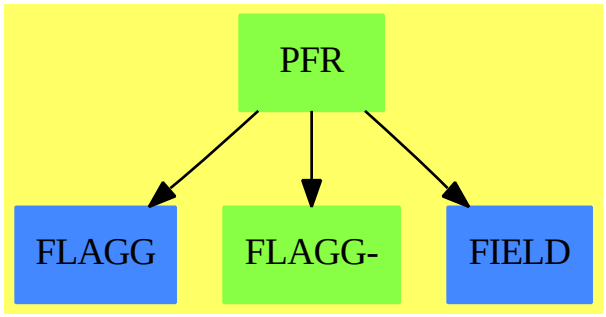
$$\frac{1}{(x+1)(x+2)^2(x+3)^3(x+4)^4}$$

The polynomials in this object have type
UnivariatePolynomial(x, Fraction Integer).

We use the primeFactor operation to create the denominator in factored form directly.

```
u : FR UP(x, FRAC INT) := reduce(*,[primeFactor(x+i,i) for i in 1..4])
                2       3       4
  (x + 1)(x + 2) (x + 3) (x + 4)
                Type: Factored UnivariatePolynomial(x,Fraction Integer)
```

These are the compact and expanded partial fractions for the quotient.



```
partialFraction(1,u)
   1     1      7     17  2         139   607  3   10115  2   391     44179
  ---    - x + --   - -- x  - 12x - ---   --- x  + ----- x  + --- x + -----
  648    4     16      8              8    324       432        4       324
 ----- + -------- + ------------------- + ---------------------------------
 x + 1          2                3                          4
         (x + 2)          (x + 3)                    (x + 4)

— domain PFR PartialFraction —

```
)abbrev domain PFR PartialFraction
++ Author: Robert S. Sutor
++ Date Created: 1986
++ Change History: 05/20/91 BMT Converted to the new library
++ Description:
++ The domain \spadtype{PartialFraction} implements partial fractions
++ over a euclidean domain \spad{R}.  This requirement on the
++ argument domain allows us to normalize the fractions.  Of
++ particular interest are the 2 forms for these fractions.  The
++ ‘‘compact’’ form has only one fractional term per prime in the
++ denominator, while the ‘‘p-adic’’ form expands each numerator
++ p-adically via the prime p in the denominator.  For computational
++ efficiency, the compact form is used, though the p-adic form may
++ be gotten by calling the function padicFraction}.  For a
++ general euclidean domain, it is not known how to factor the
++ denominator.  Thus the function partialFraction takes as its
++ second argument an element of \spadtype{Factored(R)}.

PartialFraction(R: EuclideanDomain): Cat == Capsule where
  FRR  ==> Factored R
  SUPR ==> SparseUnivariatePolynomial R

  Cat == Join(Field, Algebra R) with
    coerce: % -> Fraction R
      ++ coerce(p) sums up the components of the partial fraction and
      ++ returns a single fraction.
      ++
      ++X a:=(13/74)::PFR(INT)
      ++X a::FRAC(INT)

    coerce:  Fraction FRR -> %
      ++ coerce(f) takes a fraction with numerator and denominator in
      ++ factored form and creates a partial fraction.  It is
```

```
  ++ necessary for the parts to be factored because it is not
  ++ known in general how to factor elements of \spad{R} and
  ++ this is needed to decompose into partial fractions.
  ++
  ++X (13/74)::PFR(INT)

compactFraction: % -> %
  ++ compactFraction(p) normalizes the partial fraction \spad{p}
  ++ to the compact representation. In this form, the partial
  ++ fraction has only one fractional term per prime in the
  ++ denominator.
  ++
  ++X a:=partialFraction(1,factorial 10)
  ++X b:=padicFraction(a)
  ++X compactFraction(b)

firstDenom: % -> FRR
  ++ firstDenom(p) extracts the denominator of the first fractional
  ++ term. This returns 1 if there is no fractional part (use
  ++ wholePart from PartialFraction to get the whole part).
  ++
  ++X a:=partialFraction(1,factorial 10)
  ++X firstDenom(a)

firstNumer:  % -> R
  ++ firstNumer(p) extracts the numerator of the first fractional
  ++ term. This returns 0 if there is no fractional part (use
  ++ wholePart from PartialFraction to get the whole part).
  ++
  ++X a:=partialFraction(1,factorial 10)
  ++X firstNumer(a)

nthFractionalTerm:  (%,Integer) -> %
  ++ nthFractionalTerm(p,n) extracts the nth fractional term from
  ++ the partial fraction \spad{p}.  This returns 0 if the index
  ++ \spad{n} is out of range.
  ++
  ++X a:=partialFraction(1,factorial 10)
  ++X b:=padicFraction(a)
  ++X nthFractionalTerm(b,3)

numberOfFractionalTerms: % -> Integer
  ++ numberOfFractionalTerms(p) computes the number of fractional
  ++ terms in \spad{p}. This returns 0 if there is no fractional
  ++ part.
  ++
  ++X a:=partialFraction(1,factorial 10)
  ++X b:=padicFraction(a)
  ++X numberOfFractionalTerms(b)
```

```
    padicallyExpand: (R,R) -> SUPR
      ++ padicallyExpand(p,x) is a utility function that expands
      ++ the second argument \spad{x} ``p-adically'' in
      ++ the first.

    padicFraction: % -> %
      ++ padicFraction(q) expands the fraction p-adically in the primes
      ++ \spad{p} in the denominator of \spad{q}. For example,
      ++ \spad{padicFraction(3/(2**2)) = 1/2 + 1/(2**2)}.
      ++ Use compactFraction from PartialFraction to
      ++ return to compact form.
      ++
      ++X a:=partialFraction(1,factorial 10)
      ++X padicFraction(a)

    partialFraction: (R, FRR) -> %
      ++ partialFraction(numer,denom) is the main function for
      ++ constructing partial fractions. The second argument is the
      ++ denominator and should be factored.
      ++
      ++X partialFraction(1,factorial 10)

    wholePart: % -> R
      ++ wholePart(p) extracts the whole part of the partial fraction
      ++ \spad{p}.
      ++
      ++X a:=(74/13)::PFR(INT)
      ++X wholePart(a)

=====================================================================
Permutation Examples
=====================================================================

Permutation(S) implements the group of all bijections on a set S,
which move only a finite number of points. A permutation is considered
as a map from S into S. In particular, multiplication is defined as
composition of maps:
   pi1 * pi2 = pi1 o pi2.

We represent a permutation as two lists of equal length representing preimages
and images of moved points. I.e., fixed points do not occur in either of these
lists. This enables us to compute the set of fixed points and the set of moved
points easily.

  p := coercePreimagesImages([[1,2,3],[1,2,3]])
    1
                      Type: Permutation PositiveInteger

  movedPoints p

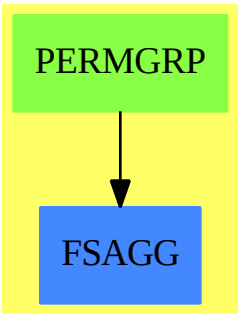
PermutationGroup examples
=====================================================================



PermutationGroup implements permutation groups acting on a set S,
i.e. all subgroups of the symmetric group of S, represented as a list
of permutations (generators). Note that therefore the objects are not
members of the Axiom category Group.

Using the idea of base and strong generators by Sims, basic routines
and algorithms are implemented so that the word problem for permutation
groups can be solved.

  generators           : %         -> L PERM S
    ++ generators(gp) returns the generators of the group gp.
  elt              : (%,NNI)   -> PERM S
    ++ elt(gp,i) returns the i-th generator of the group gp.
  random           : (%,I)     -> PERM S
    ++ random(gp,i) returns a random product of maximal i generators
    ++ of the group gp.
  random           : %         -> PERM S
    ++ random(gp) returns a random product of maximal 20 generators
    ++ of the group gp.
    ++ Note: random(gp)=random(gp,20).
  order            : %         -> NNI
    ++ order(gp) returns the order of the group gp.
  degree           : %         -> NNI
    ++ degree(gp) returns the number of points moved by all permutations
    ++ of the group gp.
  base             : %         -> L S
    ++ base(gp) returns a base for the group gp.
  strongGenerators : %         -> L PERM S
    ++ strongGenerators(gp) returns strong generators for
    ++ the group gp.
  wordsForStrongGenerators      : %         -> L L NNI
    ++ wordsForStrongGenerators(gp) returns the words for the strong
    ++ generators of the group gp in the original generators of
    ++ gp, represented by their indices in the list, given by
    ++ generators.
  coerce           : L PERM S  -> %
    ++ coerce(ls) coerces a list of permutations ls to the group
    ++ generated by this list.
  permutationGroup          : L PERM S  -> %
    ++ permutationGroup(ls) coerces a list of permutations ls to
    ++ the group generated by this list.
  orbit            : (%,S)     -> FSET S
    ++ orbit(gp,el) returns the orbit of the element el under the
    ++ group gp, i.e. the set of all points gained by applying
    ++ each group element to el.
  orbits           : %         -> FSET FSET S
    ++ orbits(gp) returns the orbits of the group gp, i.e.
    ++ it partitions the (finite) of all moved points.
  orbit            : (%,FSET S)-> FSET FSET S
    ++ orbit(gp,els) returns the orbit of the unordered
    ++ set els under the group gp.
  orbit            : (%,L S)   -> FSET L S
    ++ orbit(gp,ls) returns the orbit of the ordered
    ++ list ls under the group gp.
    ++ Note: return type is L L S temporarily because FSET L S has an error.
```

```
    -- (GILT DAS NOCH?)
  member?          : (PERM S, %)-> B
    ++ member?(pp,gp) answers the question, whether the
    ++ permutation pp is in the group gp or not.
  wordInStrongGenerators : (PERM S, %)-> L NNI
    ++ wordInStrongGenerators(p,gp) returns the word for the
    ++ permutation p in the strong generators of the group gp,
    ++ represented by the indices of the list, given by strongGenerators.
  wordInGenerators : (PERM S, %)-> L NNI
    ++ wordInGenerators(p,gp) returns the word for the permutation p
    ++ in the original generators of the group gp,
    ++ represented by the indices of the list, given by generators.
  movedPoints      : %         -> FSET S
    ++ movedPoints(gp) returns the points moved by the group gp.
  "<"              : (%,%)     -> B
    ++ gp1 < gp2 returns true if and only if gp1
    ++ is a proper subgroup of gp2.
  "<="             : (%,%)     -> B
    ++ gp1 <= gp2 returns true if and only if gp1
    ++ is a subgroup of gp2.
    ++ Note: because of a bug in the parser you have to call this
    ++ function explicitly by gp1 <=$(PERMGRP S) gp2.
    -- (GILT DAS NOCH?)
  initializeGroupForWordProblem : %   -> Void
    ++ initializeGroupForWordProblem(gp) initializes the group gp
    ++ for the word problem.
    ++ Notes: it calls the other function of this name with parameters
    ++ 0 and 1: initializeGroupForWordProblem(gp,0,1).
    ++ Notes: (1) be careful: invoking this routine will destroy the
    ++ possibly information about your group (but will recompute it again)
    ++ (2) users need not call this function normally for the soultion of
    ++ the word problem.
  initializeGroupForWordProblem :(%,I,I) -> Void
    ++ initializeGroupForWordProblem(gp,m,n) initializes the group
    ++ gp for the word problem.
    ++ Notes: (1) with a small integer you get shorter words, but the
    ++ routine takes longer than the standard routine for longer words.
    ++ (2) be careful: invoking this routine will destroy the possibly stored
    ++ information about your group (but will recompute it again).
    ++ (3) users need not call this function normally for the soultion of
    ++ the word problem.

domain HACKPI Pi

What is the purpose of the HACKPI domain?

HACKPI is a hack provided for the benefit of the axiom interpreter. As a mathematical type, it is the simple transcendental extension `Q(\pi)` of the rational numbers. This type allows interactive users to use the name `'%pi'` without a type both where a numerical value is expected [as in `draw(sin x,x=-%pi..%pi)`] or when the exact symbolic value is meant. The interpreter defaults a typeless `%pi` to HACKPI and then uses the various conversions to cast it further as required by the context.

One could argue that it is unfair to single `%pi` out from other constants, but it occurs frequently enough in school examples (specially for graphs) so it was worth a special hack. In a non-interactive environment (library), HACKPI would not exist.

— domain ACPLOT PlaneAlgebraicCurvePlot —

```
)abbrev domain ACPLOT PlaneAlgebraicCurvePlot
++ Author: Clifton J. Williamson and Timothy Daly
++ Date Created: Fall 1988
++ Date Last Updated: 27 April 1990
```

```
++ Description:
++ Plot a NON-SINGULAR plane algebraic curve p(x,y) = 0.

PlaneAlgebraicCurvePlot(): PlottablePlaneCurveCategory _
 with

  makeSketch:(Polynomial Integer,Symbol,Symbol,Segment Fraction Integer,_
              Segment Fraction Integer) -> %
     ++ makeSketch(p,x,y,a..b,c..d) creates an ACPLOT of the
     ++ curve \spad{p = 0} in the region a <= x <= b, c <= y <= d.
     ++ More specifically, 'makeSketch' plots a non-singular algebraic curve
     ++ \spad{p = 0} in an rectangular region xMin <= x <= xMax,
     ++ yMin <= y <= yMax. The user inputs
     ++ \spad{makeSketch(p,x,y,xMin..xMax,yMin..yMax)}.
     ++ Here p is a polynomial in the variables x and y with
     ++ integer coefficients (p belongs to the domain
     ++ \spad{Polynomial Integer}). The case
     ++ where p is a polynomial in only one of the variables is
     ++ allowed.  The variables x and y are input to specify the
     ++ the coordinate axes.  The horizontal axis is the x-axis and
     ++ the vertical axis is the y-axis.  The rational numbers
     ++ xMin,...,yMax specify the boundaries of the region in
     ++ which the curve is to be plotted.
     ++
     ++X makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACPLOT

  refine:(%,DoubleFloat) -> %
     ++ refine(p,x) is not documented
     ++
     ++X sketch:=makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACPLOT
     ++X refined:=refine(sketch,0.1)

-- p0=(x0,y0) and p1=(x1,y1) are the last two points on the curve.
-- The function computes the next point on the curve.
-- The function determines if the next point is a critical point
-- or a boundary point.
-- The function returns a record of the form
-- Record(newPt:Point DoubleFloat,type:String).
-- If the new point is a boundary point, then 'type' is
-- "boundary point" and 'newPt' is a boundary point to be
-- deleted from the list of boundary points yet to be plotted.
-- Similarly, if the new point is a critical point, then 'type' is
-- "critical point" and 'newPt' is a critical point to be
-- deleted from the list of critical points yet to be plotted.
-- If the new point is neither a critical point nor a boundary
-- point, then 'type' is "nothing in particular".

Plot examples
========================================================================

The Plot (PLOT) domain supports plotting of functions defined over a
real number system. Plot is limited to 2 dimensional plots.

The function plot: (F -> F,R) -> % plots the function f(x) on the
interval a..b. So we need to define a function that maps from
DoubleFloat to DoubleFloat:

  fp:=(t:DFLOAT):DFLOAT +-> sin(t)

and then feed it to the plot function with a Segment DoubleFloat

  plot(fp,-1.0..1.0)$PLOT
```

```

)abbrev domain PLOT Plot
++ Author: Michael Monagan (revised by Clifton J. Williamson)
++ Date Created: Jan 1988
++ Date Last Updated: 30 Nov 1990 by Jonathan Steinbach
++ Description:
++ The Plot domain supports plotting of functions defined over a
++ real number system.  A real number system is a model for the real
++ numbers and as such may be an approximation.  For example
++ floating point numbers and infinite continued fractions.
++ The facilities at this point are limited to 2-dimensional plots
++ or either a single function or a parametric function.

--% function plots

    plot: (F -> F,R) -> %
      ++ plot(f,a..b) plots the function \spad{f(x)}
      ++ on the interval \spad{[a,b]}.
      ++
      ++X fp:=(t:DFLOAT):DFLOAT +-> sin(t)
      ++X plot(fp,-1.0..1.0)$PLOT

    plot: (F -> F,R,R) -> %
      ++ plot(f,a..b,c..d) plots the function \spad{f(x)} on the interval
      ++ \spad{[a,b]}; y-range of \spad{[c,d]} is noted in Plot object.

--% multiple function plots

    plot: (L(F -> F),R) -> %
      ++ plot([f1,...,fm],a..b) plots the functions \spad{y = f1(x)},...,
      ++ \spad{y = fm(x)} on the interval \spad{a..b}.
    plot: (L(F -> F),R,R) -> %
      ++ plot([f1,...,fm],a..b,c..d) plots the functions \spad{y = f1(x)},...,
      ++ \spad{y = fm(x)} on the interval \spad{a..b}; y-range of \spad{[c,d]} is
      ++ noted in Plot object.

--% parametric plots

    plot: (F -> F,F -> F,R) -> %
      ++ plot(f,g,a..b) plots the parametric curve \spad{x = f(t)},
      ++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}.
    plot: (F -> F,F -> F,R,R,R) -> %
      ++ plot(f,g,a..b,c..d,e..f) plots the parametric curve \spad{x = f(t)},
      ++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}; x-range
      ++ of \spad{[c,d]} and y-range of \spad{[e,f]} are noted in Plot object.

--% parametric plots

    pointPlot: (F -> P,R) -> %
      ++ pointPlot(t +-> (f(t),g(t)),a..b) plots the parametric curve
      ++ \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
      ++ \spad{[a,b]}.
    pointPlot: (F -> P,R,R,R) -> %
```

```
      ++ pointPlot(t +-> (f(t),g(t)),a..b,c..d,e..f) plots the parametric
      ++ curve \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
      ++ \spad{[a,b]}; x-range of \spad{[c,d]} and y-range of \spad{[e,f]}
      ++ are noted in Plot object.

--% polar plots

    plotPolar: (F -> F,R) -> %
      ++ plotPolar(f,a..b) plots the polar curve \spad{r = f(theta)} as
      ++ theta ranges over the interval \spad{[a,b]}; this is the same as
      ++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

    plotPolar: (F -> F) -> %
      ++ plotPolar(f) plots the polar curve \spad{r = f(theta)} as theta
      ++ ranges over the interval \spad{[0,2*%pi]}; this is the same as
      ++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

    plot: (%,R) -> %              -- change the range
        ++ plot(x,r) is not documented
    parametric?: % -> B
      ++ parametric? determines whether it is a parametric plot?

    zoom: (%,R) -> %
        ++ zoom(x,r) is not documented
    zoom: (%,R,R) -> %
        ++ zoom(x,r,s) is not documented
    refine: (%,R) -> %
        ++ refine(x,r) is not documented
    refine: % -> %
      ++ refine(p) performs a refinement on the plot p

    tRange: % -> R
      ++ tRange(p) returns the range of the parameter in a parametric plot p

    minPoints: () -> I
      ++ minPoints() returns the minimum number of points in a plot
    setMinPoints: I -> I
      ++ setMinPoints(i) sets the minimum number of points in a plot to i
    maxPoints: () -> I
      ++ maxPoints() returns the maximum number of points in a plot
    setMaxPoints: I -> I
      ++ setMaxPoints(i) sets the maximum number of points in a plot to i
    screenResolution: () -> I
      ++ screenResolution() returns the screen resolution
    setScreenResolution: I -> I
      ++ setScreenResolution(i) sets the screen resolution to i
    adaptive?: () -> B
      ++ adaptive?() determines whether plotting be done adaptively
    setAdaptive: B -> B
      ++ setAdaptive(true) turns adaptive plotting on
```

```
      ++ \spad{setAdaptive(false)} turns adaptive plotting off
    numFunEvals: () -> I
      ++ numFunEvals() returns the number of points computed
    debug: B -> B

========================================================================
Plot3D examples
========================================================================

Plot3D supports parametric plots defined over a real number system.
A real number system is a model for the real numbers and as such may
be an approximation.  For example, floating point numbers and infinite
continued fractions are real number systems. The facilities at this
point are limited to 3-dimensional parametric plots.

++ Description:
++ This domain provides the internal representation
++ of polynomials in non-commutative variables written
++ over the Poincare-Birkhoff-Witt basis.
++ See the \spadtype{XPBWPolynomial} domain constructor.
++ See Free Lie Algebras by C. Reutenauer
++ (Oxford science publications).

PoincareBirkhoffWittLyndonBasis(VarSet: OrderedSet): Public == Private where
   WORD    ==> OrderedFreeMonoid(VarSet)
   LWORD   ==> LyndonWord(VarSet)
   LWORDS  ==> List(LWORD)
   PI      ==> PositiveInteger
   NNI     ==> NonNegativeInteger
   EX      ==> OutputForm

   Public == Join(OrderedSet, RetractableTo LWORD) with
      1: constant -> %
         ++ \spad{1} returns the empty list.
      coerce       : $ -> WORD
```

```
      ++ \spad{coerce([l1]*[l2]*...[ln])} returns the word \spad{l1*l2*...*ln},
      ++ where \spad{[l_i]} is the backeted form of the Lyndon word \spad{l_i}.
    coerce       : VarSet -> $
      ++ \spad{coerce(v)} return \spad{v}
    first        : $ -> LWORD
      ++ \spad{first([l1]*[l2]*...[ln])} returns the Lyndon word \spad{l1}.
    length       : $ -> NNI
      ++ \spad{length([l1]*[l2]*...[ln])} returns the length of the word \spad{l1*l2*...*ln}.
    listOfTerms  : $ -> LWORDS
      ++ \spad{listOfTerms([l1]*[l2]*...[ln])} returns the list of words \spad{l1, l2, .... ln}.
    rest         : $ -> $
      ++ \spad{rest([l1]*[l2]*...[ln])} returns the list \spad{l2, .... ln}.
    retractable? : $ -> Boolean
      ++ \spad{retractable?([l1]*[l2]*...[ln])} returns true iff \spad{n}  equals \spad{1}.
    varList      : $ -> List VarSet
      ++ \spad{varList([l1]*[l2]*...[ln])} returns the list of
      ++ variables in the word \spad{l1*l2*...*ln}.

========================================================================
Polynomial examples
========================================================================

The domain constructor Polynomial (abbreviation: POLY) provides
polynomials with an arbitrary number of unspecified variables.

It is used to create the default polynomial domains in Axiom.  Here
the coefficients are integers.

  x + 1
    x + 1
                          Type: Polynomial Integer

Here the coefficients have type Float.

  z - 2.3
    z - 2.3
                           Type: Polynomial Float
```

And here we have a polynomial in two variables with coefficients which
have type Fraction Integer.

```
  y**2 - z + 3/4
          2   3
    - z + y  + -
               4
                              Type: Polynomial Fraction Integer
```

The representation of objects of domains created by Polynomial is that
of recursive univariate polynomials. The term univariate means "one
variable". The term multivariate means "possibly more than one variable".

This recursive structure is sometimes obvious from the display of a polynomial.

```
  y **2 + x*y + y
     2
    y  + (x + 1)y
                              Type: Polynomial Integer
```

In this example, you see that the polynomial is stored as a polynomial
in y with coefficients that are polynomials in x with integer coefficients.
In fact, you really don't need to worry about the representation unless you
are working on an advanced application where it is critical. The polynomial
types created from DistributedMultivariatePolynomial and
NewDistributedMultivariatePolynomial are stored and displayed in a
non-recursive manner.

You see a "flat" display of the above polynomial by converting to
one of those types.

```
  % :: DMP([y,x],INT)
     2
    y  + y x + y
                   Type: DistributedMultivariatePolynomial([y,x],Integer)
```

We will demonstrate many of the polynomial facilities by using two
polynomials with integer coefficients.

By default, the interpreter expands polynomial expressions, even if they
are written in a factored format.

```
  p := (y-1)**2 * x * z
        2
    (x y  - 2x y + x)z
                   Type: Polynomial Integer
```

See Factored to see how to create objects in factored form directly.

```
  q := (y-1) * x * (z+5)
```

```
    (x y - x)z + 5x y - 5x
                    Type: Polynomial Integer
```

The fully factored form can be recovered by using factor.

```
  factor(q)
    x(y - 1)(z + 5)
                    Type: Factored Polynomial Integer
```

This is the same name used for the operation to factor integers. Such reuse of names is called overloading and makes it much easier to think of solving problems in general ways. Axiom facilities for factoring polynomials created with Polynomial are currently restricted to the integer and rational number coefficient cases.

The standard arithmetic operations are available for polynomials.

```
  p - q**2
         2 2     2     2  2          2      2       2             2
     (- x y  + 2x y - x )z  + ((- 10x  + x)y  + (20x  - 2x)y - 10x  + x)z
   +
          2 2      2       2
     - 25x y  + 50x y - 25x
                    Type: Polynomial Integer
```

The operation gcd is used to compute the greatest common divisor of two polynomials.

```
  gcd(p,q)
    x y - x
                    Type: Polynomial Integer
```

In the case of p and q, the gcd is obvious from their definitions. We factor the gcd to show this relationship better.

```
  factor %
    x(y - 1)
                    Type: Factored Polynomial Integer
```

The least common multiple is computed by using lcm.

```
  lcm(p,q)
       2             2        2
    (x y  - 2x y + x)z  + (5x y  - 10x y + 5x)z
                    Type: Polynomial Integer
```

Use content to compute the greatest common divisor of the coefficients of the polynomial.

```
  content p
```

```
   1
                  Type: PositiveInteger
```

Many of the operations on polynomials require you to specify a variable. For example, resultant requires you to give the variable in which the polynomials should be expressed.

This computes the resultant of the values of p and q, considering them as polynomials in the variable z. They do not share a root when thought of as polynomials in z.

```
  resultant(p,q,z)
       2 3      2 2      2      2
    5x y  - 15x y  + 15x y - 5x
                  Type: Polynomial Integer
```

This value is 0 because as polynomials in x the polynomials have a common root.

```
  resultant(p,q,x)
    0
                  Type: Polynomial Integer
```

The data type used for the variables created by Polynomial is Symbol. As mentioned above, the representation used by Polynomial is recursive and so there is a main variable for nonconstant polynomials.

The operation mainVariable returns this variable. The return type is actually a union of Symbol and "failed".

```
  mainVariable p
    z
                  Type: Union(Symbol,...)
```

The latter branch of the union is be used if the polynomial has no variables, that is, is a constant.

```
  mainVariable(1 :: POLY INT)
    "failed"
                  Type: Union("failed",...)
```

You can also use the predicate ground? to test whether a polynomial is in fact a member of its ground ring.

```
  ground? p
    false
                  Type: Boolean

  ground?(1 :: POLY INT)
    true
```

```
                  Type: Boolean
```

The complete list of variables actually used in a particular polynomial is returned by variables. For constant polynomials, this list is empty.

```
  variables p
    [z,y,x]
                  Type: List Symbol
```

The degree operation returns the degree of a polynomial in a specific variable.

```
  degree(p,x)
    1
                  Type: PositiveInteger

  degree(p,y)
    2
                  Type: PositiveInteger

  degree(p,z)
    1
                  Type: PositiveInteger
```

If you give a list of variables for the second argument, a list of the degrees in those variables is returned.

```
  degree(p,[x,y,z])
    [1,2,1]
                  Type: List NonNegativeInteger
```

The minimum degree of a variable in a polynomial is computed using minimumDegree.

```
  minimumDegree(p,z)
    1
                  Type: PositiveInteger
```

The total degree of a polynomial is returned by totalDegree.

```
  totalDegree p
    4
                  Type: PositiveInteger
```

It is often convenient to think of a polynomial as a leading monomial plus the remaining terms.

```
  leadingMonomial p
        2
     x y z
                  Type: Polynomial Integer
```

```
The reductum operation returns a polynomial consisting of the sum of
the monomials after the first.

  reductum p
    (- 2x y + x)z
                    Type: Polynomial Integer

These have the obvious relationship that the original polynomial is
equal to the leading monomial plus the reductum.

  p - leadingMonomial p - reductum p
    0
                    Type: Polynomial Integer

The value returned by leadingMonomial includes the coefficient of that term.
This is extracted by using leadingCoefficient on the original polynomial.

  leadingCoefficient p
    1
                    Type: PositiveInteger

The operation eval is used to substitute a value for a variable in a
polynomial.

  p
        2
    (x y  - 2x y + x)z
                    Type: Polynomial Integer

This value may be another variable, a constant or a polynomial.

  eval(p,x,w)
        2
    (w y  - 2w y + w)z
                    Type: Polynomial Integer

  eval(p,x,1)
      2
    (y  - 2y + 1)z
                    Type: Polynomial Integer

Actually, all the things being substituted are just polynomials,
some more trivial than others.

  eval(p,x,y^2 - 1)
      4     3
    (y  - 2y  + 2y - 1)z
                    Type: Polynomial Integer
```

Derivatives are computed using the D operation.

```
  D(p,x)
      2
    (y  - 2y + 1)z
                   Type: Polynomial Integer
```

The first argument is the polynomial and the second is the variable.

```
  D(p,y)
    (2x y - 2x)z
                   Type: Polynomial Integer
```

Even if the polynomial has only one variable, you must specify it.

```
  D(p,z)
       2
    x y  - 2x y + x
                   Type: Polynomial Integer
```

Integration of polynomials is similar and the integrate operation is used.

Integration requires that the coefficients support division. Axiom converts polynomials over the integers to polynomials over the rational numbers before integrating them.

```
  integrate(p,y)
     1    3      2
    (- x y  - x y  + x y)z
     3
                  Type: Polynomial Fraction Integer
```

It is not possible, in general, to divide two polynomials. In our example using polynomials over the integers, the operation monicDivide divides a polynomial by a monic polynomial (that is, a polynomial with leading coefficient equal to 1). The result is a record of the quotient and remainder of the division.

You must specify the variable in which to express the polynomial.

```
  qr := monicDivide(p,x+1,x)
                2                            2
    [quotient= (y  - 2y + 1)z,remainder= (- y  + 2y - 1)z]
     Type: Record(quotient: Polynomial Integer,remainder: Polynomial Integer)
```

The selectors of the components of the record are quotient and remainder. Issue this to extract the remainder.

```
  qr.remainder
        2
```

```
    (- y  + 2y - 1)z
                        Type: Polynomial Integer
```

Now that we can extract the components, we can demonstrate the relationship among them and the arguments to our original expression qr := monicDivide(p,x+1,x).

```
  p - ((x+1) * qr.quotient + qr.remainder)
    0
                        Type: Polynomial Integer
```

If the / operator is used with polynomials, a fraction object is created. In this example, the result is an object of type Fraction Polynomial Integer.

```
  p/q
    (y - 1)z
    --------
      z + 5
                        Type: Fraction Polynomial Integer
```

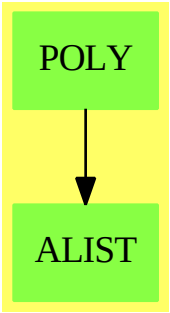
If you use rational numbers as polynomial coefficients, the resulting object is of type Polynomial Fraction Integer.

```
  (2/3) * x**2 - y + 4/5
         2  2   4
    - y + - x  + -
         3      5
                        Type: Polynomial Fraction Integer
```

This can be converted to a fraction of polynomials and back again, if required.

```
  % :: FRAC POLY INT
              2
    - 15y + 10x  + 12
    -----------------
            15
                        Type: Fraction Polynomial Integer

  % :: POLY FRAC INT
         2  2   4
    - y + - x  + -
         3      5
                        Type: Polynomial Fraction Integer
```



To convert the coefficients to floating point, map the numeric operation on the coefficients of the polynomial.

```
  map(numeric,%)
```

```
    - 1.0 y + 0.6666666666 6666666667 x  + 0.8
                        Type: Polynomial Float

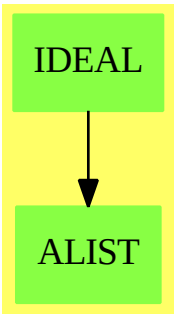
PolynomialIdeals examples
=====================================================================

This domain represents polynomial ideals with coefficients in any
field and supports the basic ideal operations, including intersection
sum and quotient.



An ideal is represented by a list of polynomials (the generators of
the ideal) and a boolean that is true if the generators are a Groebner
basis.

The algorithms used are based on Groebner basis computations. The
ordering is determined by the datatype of the input polynomials.
Users may use refinements of total degree orderings.

C == SetCategory with

  "*"             :  (Ideal,Ideal)        -> Ideal
    ++ I*J computes the product of the ideal I and J.
  "**"            :   (Ideal,NNI)         -> Ideal
    ++ I**n computes the nth power of the ideal I.
  "+"             :  (Ideal,Ideal)        -> Ideal
    ++ I+J computes the ideal generated by the union of I and J.
  one?            :     Ideal             -> Boolean
    ++ one?(I) tests whether the ideal I is the unit ideal,
    ++ i.e. contains 1.
  zero?           :     Ideal             -> Boolean
    ++ zero?(I) tests whether the ideal I is the zero ideal
  element?        :  (DPoly,Ideal)        -> Boolean
    ++ element?(f,I) tests whether the polynomial f belongs to
    ++ the ideal I.
  in?             :  (Ideal,Ideal)        -> Boolean
    ++ in?(I,J) tests if the ideal I is contained in the ideal J.
  inRadical?      :  (DPoly,Ideal)        -> Boolean
    ++ inRadical?(f,I) tests if some power of the polynomial f
    ++ belongs to the ideal I.
  zeroDim?        : (Ideal,List VarSet)   -> Boolean
    ++ zeroDim?(I,lvar) tests if the ideal I is zero dimensional, i.e.
    ++ all its associated primes are maximal,
    ++ in the ring \spad{F[lvar]}
  zeroDim?        :     Ideal             -> Boolean
    ++ zeroDim?(I) tests if the ideal I is zero dimensional, i.e.
    ++ all its associated primes are maximal,
    ++ in the ring \spad{F[lvar]},
    ++ where lvar are the variables appearing  in I
  intersect       :  (Ideal,Ideal)        -> Ideal
    ++ intersect(I,J) computes the intersection of the ideals I and J.
  intersect       :   List(Ideal)         -> Ideal
    ++ intersect(LI) computes the intersection of the list of ideals LI.
  quotient        :  (Ideal,Ideal)        -> Ideal
    ++ quotient(I,J) computes the quotient of the ideals I and J,
    ++ \spad{(I:J)}.
  quotient        :  (Ideal,DPoly)        -> Ideal
    ++ quotient(I,f) computes the quotient of the ideal I by the principal
    ++ ideal generated by the polynomial f, \spad{(I:(f))}.
  groebner        :     Ideal             -> Ideal
    ++ groebner(I) returns a set of generators of I that are a
    ++ Groebner basis for I.
```

```
  generalPosition :  (Ideal,List VarSet)      -> GenMPos
    ++ generalPosition(I,listvar) perform a random linear
    ++ transformation on the variables in listvar and returns
    ++ the transformed ideal along with the change of basis matrix.
  backOldPos      :     GenMPos           -> Ideal
    ++ backOldPos(genPos) takes the result
    ++ produced by generalPosition from PolynomialIdeals
    ++ and performs the inverse transformation, returning the original ideal
    ++ \spad{backOldPos(generalPosition(I,listvar))} = I.
  dimension       : (Ideal,List VarSet)   -> Z
    ++ dimension(I,lvar) gives the dimension of the ideal I,
    ++ in the ring \spad{F[lvar]}
  dimension       :      Ideal            -> Z
    ++ dimension(I) gives the dimension of the ideal I.
    ++ in the ring \spad{F[lvar]}, where lvar are the variables
    ++ appearing  in I
  leadingIdeal    :     Ideal             -> Ideal
    ++ leadingIdeal(I) is the ideal generated by the
    ++ leading terms of the elements of the ideal I.
  ideal           :   List DPoly          ->  Ideal
    ++ ideal(polyList) constructs the ideal generated by the list
    ++ of polynomials polyList.
  groebnerIdeal       :   List DPoly          ->  Ideal
    ++ groebnerIdeal(polyList) constructs the ideal generated by the list
    ++ of polynomials polyList which are assumed to be a Groebner
    ++ basis.
    ++ Note: this operation avoids a Groebner basis computation.
  groebner?           :     Ideal             ->  Boolean
    ++ groebner?(I) tests if the generators of the ideal I are a
    ++ Groebner basis.
  generators      :     Ideal             ->  List DPoly
    ++ generators(I) returns a list of generators for the ideal I.
  coerce          :   List DPoly          ->  Ideal
    ++ coerce(polyList) converts the list of polynomials polyList
    ++ to an ideal.

  saturate        :  (Ideal,DPoly)        -> Ideal
    ++ saturate(I,f) is the saturation of the ideal I
    ++ with respect to the multiplicative
    ++ set generated by the polynomial f.
  saturate        :(Ideal,DPoly,List VarSet)  -> Ideal
    ++ saturate(I,f,lvar) is the saturation with respect to the prime
    ++ principal ideal which is generated by f in the polynomial ring
    ++ \spad{F[lvar]}.
  if VarSet has ConvertibleTo Symbol then
    relationsIdeal  :    List DPoly         -> ST
      ++ relationsIdeal(polyList) returns the ideal of relations among the
      ++ polynomials in polyList.

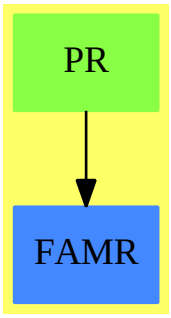
PolynomialRing examples
=====================================================================



This domain represents generalized polynomials with coefficients
(from a not necessarily commutative ring), and terms indexed by their
exponents (from an arbitrary ordered abelian monoid).

This type is used, for example, by the DistributedMultivariatePolynomial
domain where the exponent domain is a direct product of non negative integers.

=====================================================================
```

```
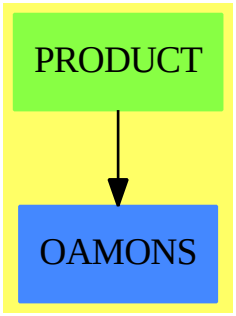
Product examples
================================================================

The direct product of two functions over the same domain is
another function over that domain whose co-domain is the product
of their co-domains.

So we can define two functions, f and g, that go from INT -> INT

   f:=(x:INT):INT +-> 3*x
   g:=(x:INT):INT +-> x^3

so
    f(3) is 9
    g(3) is 27



and we can construct the direct product of those functions h=f,g

   h(x:INT):Product(INT,INT) == makeprod(f x, g x)

so
   h(3) is (9,27)

=====================================================================
PseudoAlgebraicClosureOfFiniteField examples
=====================================================================

This domain implement  dynamic extension using the simple notion of
tower extensions. A tower extension T  of the ground  field K is any
sequence of field extension
   (T : K_0, K_1, ..., K_i...,K_n)
where K_0 = K and for i =1,2,...,n, K_i is an extension of K_{i-1}
of degree > 1 and defined by an irreducible polynomial p(Z) in K_{i-1}.

Two towers
   (T_1: K_01, K_11,...,K_i1,...,K_n1)
and
   (T_2: K_02, K_12,...,K_i2,...,K_n2)
are said to be related if
   T_1 <= T_2 (or T_1 >= T_2),
that is if
   K_i1 = K_i2 for i=1,2,...,n1
(or i=1,2,...,n2). Any algebraic operations defined for several elements
are only defined if all of the concerned elements are comming from
a set of related tour extensions.

=====================================================================
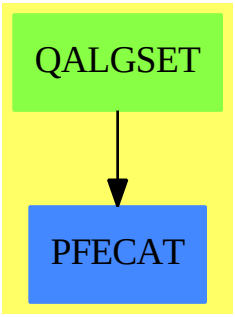
QuasiAlgebraicSet examples
=====================================================================

QuasiAlgebraicSet constructs a domain representing quasi-algebraic
sets, which is the intersection of a Zariski closed set, defined as
the common zeros of a given list of polynomials (the defining
polynomials for equations), and a principal Zariski open set,
defined as the complement of the common zeros of a polynomial f
(the defining polynomial for the inequation).

This domain provides simplification of a user-given representation
using groebner basis computations.
```



```
There are two simplification routines: the first function idealSimplify
uses groebner basis of ideals alone, while the second, simplify uses both
groebner basis and factorization. The resulting defining equations L
always form a groebner basis, and the resulting defining
inequation f is always reduced. The function simplify may be applied
several times if desired. A third simplification routine
radicalSimplify is provided in QuasiAlgebraicSet2 for comparison study only,
as it is inefficient compared to the other two, as well as is restricted
to only certain coefficient domains.  For detail analysis and a comparison
of the three methods, please consult the reference cited.

A polynomial function q defined on the quasi-algebraic set is equivalent
to its reduced form with respect to L.  While this may be obtained using
the usual normal form algorithm, there is no canonical form for q.

The ordering in groebner basis computation is determined by the data
type of the input polynomials.  If it is possible we suggest to use
refinements of total degree orderings.

++            J. Sym. Comp., April, 1992
++ Description:
++ \spadtype{QuasiAlgebraicSet} constructs a domain representing
++ quasi-algebraic sets, which is the intersection of a Zariski
++ closed set, defined as the common zeros of a given list of
++ polynomials (the defining polynomials for equations), and a principal
++ Zariski open set, defined as the complement of the common
++ zeros of a polynomial f (the defining polynomial for the inequation).
++ This domain provides simplification of a user-given representation
++ using groebner basis computations.
++ There are two simplification routines: the first function
++ \spadfun{idealSimplify}  uses groebner
++ basis of ideals alone, while the second, \spadfun{simplify} uses both
++ groebner basis and factorization.  The resulting defining equations L
++ always form a groebner basis, and the resulting defining
++ inequation f is always reduced.  The function \spadfun{simplify} may
++ be applied several times if desired.   A third simplification
++ routine \spadfun{radicalSimplify} is provided in
++ \spadtype{QuasiAlgebraicSet2}  for comparison study only,
++ as it is inefficient compared to the other two, as well as is
++ restricted to only certain coefficient domains.  For detail analysis
++ and a comparison of the three methods, please consult the reference
++ cited.
++
++ A polynomial function q defined on the quasi-algebraic set
++ is equivalent to its reduced form with respect to L.  While
++ this may be obtained using the usual normal form
++ algorithm, there is no canonical form for q.
++
++ The ordering in groebner basis computation is determined by
++ the data type of the input polynomials.  If it is possible
++ we suggest to use refinements of total degree orderings.

QuasiAlgebraicSet(R, Var,Expon,Dpoly) : C == T
 where
   R         :  GcdDomain
   Expon     :  OrderedAbelianMonoidSup
   Var       :  OrderedSet
   Dpoly     :  PolynomialCategory(R,Expon,Var)
   NNI       ==> NonNegativeInteger
   newExpon  ==> Product(NNI,Expon)
   newPoly   ==> PolynomialRing(R,newExpon)
   Ex        ==> OutputForm
   mrf       ==> MultivariateFactorize(Var,Expon,R,Dpoly)
   Status    ==> Union(Boolean,"failed") -- empty or not, or don't know
```

```
 C == Join(SetCategory, CoercibleTo OutputForm) with
--- should be Object instead of SetCategory, bug in LIST Object ---
--- equality is not implemented ---
   empty: () -> $
     ++ empty() returns the empty quasi-algebraic set
   quasiAlgebraicSet:   (List Dpoly, Dpoly) -> $
     ++ quasiAlgebraicSet(pl,q) returns the quasi-algebraic set
     ++ with defining equations p = 0 for p belonging to the list pl, and
     ++ defining inequation q ^= 0.
   status: $ -> Status
     ++ status(s) returns true if the quasi-algebraic set is empty,
     ++ false if it is not, and "failed" if not yet known
   setStatus: ($, Status) -> $
     ++ setStatus(s,t) returns the same representation for s, but
     ++ asserts the following: if t is true, then s is empty,
     ++ if t is false, then s is non-empty, and if t = "failed",
     ++ then no assertion is made (that is, "don't know").
     ++ Note: for internal use only, with care.
   empty?          :   $   -> Boolean
     ++ empty?(s) returns
     ++ true if the quasialgebraic set s has no points,
     ++ and false otherwise.
   definingEquations: $ -> List Dpoly
     ++ definingEquations(s) returns a list of defining polynomials
     ++ for equations, that is, for the Zariski closed part of s.
   definingInequation: $ -> Dpoly
     ++ definingInequation(s) returns a single defining polynomial for the
     ++ inequation, that is, the Zariski open part of s.
   idealSimplify:$ -> $
     ++ idealSimplify(s) returns a different and presumably simpler
     ++ representation of s with the defining polynomials for the
     ++ equations
     ++ forming a groebner basis, and the defining polynomial for the
     ++ inequation reduced with respect to the basis, using Buchberger's
     ++ algorithm.
   if (R has EuclideanDomain) and (R has CharacteristicZero) then
     simplify:$ -> $
       ++ simplify(s) returns a different and presumably simpler
       ++ representation of s with the defining polynomials for the
       ++ equations
       ++ forming a groebner basis, and the defining polynomial for the
       ++ inequation reduced with respect to the basis, using a heuristic
       ++ algorithm based on factoring.

=====================================================================
Quaternion examples
=====================================================================

The domain constructor Quaternion implements quaternions over
commutative rings.

The basic operation for creating quaternions is quatern.  This is a
quaternion over the rational numbers.

  q := quatern(2/11,-8,3/4,1)
     2        3
    -- - 8i + - j + k
    11        4
```

```
                        Type: Quaternion Fraction Integer
```

The four arguments are the real part, the i imaginary part, the j imaginary part, and the k imaginary part, respectively.

```
  [real q, imagI q, imagJ q, imagK q]
      2     3
    [--,- 8,-,1]
     11     4
                        Type: List Fraction Integer
```

Because q is over the rationals (and nonzero), you can invert it.

```
  inv q
      352     15488      484       1936
    ------ + ------ i - ----- j - ------ k
    126993   126993     42331     126993
                        Type: Quaternion Fraction Integer
```

The usual arithmetic (ring) operations are available

```
  q^6
      2029490709319345   48251690851     144755072553     48251690851
    - ---------------- - ----------- i + ------------ j + ----------- k
          7256313856        1288408         41229056         10307264
                        Type: Quaternion Fraction Integer

  r := quatern(-2,3,23/9,-89); q + r
      20        119
    - -- - 5i + --- j - 88k
      11         36
                        Type: Quaternion Fraction Integer
```

In general, multiplication is not commutative.

```
  q * r - r * q
      2495             817
    - ---- i - 1418j - --- k
       18               18
                         Type: Quaternion Fraction Integer
```

There are no predefined constants for the imaginary i, j, and k parts, but you can easily define them.

```
  i:=quatern(0,1,0,0)
    i
                         Type: Quaternion Integer

  j:=quatern(0,0,1,0)
    j
```

```
                        Type: Quaternion Integer

  k:=quatern(0,0,0,1)
    k
                        Type: Quaternion Integer
```

These satisfy the normal identities.

```
  [i*i, j*j, k*k, i*j, j*k, k*i, q*i]
                              2         3
     [- 1,- 1,- 1,k,i,j,8 + -- i + j - - k]
                             11         4
                         Type: List Quaternion Fraction Integer
```

The norm is the quaternion times its conjugate.

```
  norm q
    126993
    ------
     1936
                         Type: Fraction Integer

  conjugate q
      2        3
     -- + 8i - - j - k
     11        4
                         Type: Quaternion Fraction Integer

  q * %
     126993
     ------
      1936
                         Type: Quaternion Fraction Integer
```

==========================================================================
Queue examples
==========================================================================

A Queue object is represented as a list ordered by first-in, first-out.
It operates like a line of people, where the "next" person is the one
at the front of the line.

Here we create an queue of integers from a list. Notice that the
order in the list is the order in the queue.

   a:Queue INT:= queue [1,2,3,4,5]
      [1,2,3,4,5]

We can remove the top of the queue using dequeue!:

   dequeue! a
      1

Notice that the use of dequeue! is destructive (destructive operations
in Axiom usually end with ! to indicate that the underylying data
structure is changed).

   a
      [2,3,4,5]

The extract! operation is another name for the pop! operation and
has the same effect. This operation treats the queue as a BagAggregate:

   extract! a
      2

and you can see that it also has destructively modified the queue:

   a
      [3,4,5]

Next we use enqueue! to add a new element to the end of the queue:

   push!(9,a)
      9

Again, the push! operation is destructive so the queue is changed:

   a
```

```
      [3,4,5,9]

Another name for enqueue! is insert!, which treats the queue as a
BagAggregate:

   insert!(8,a)
      [3,4,5,9,8]

and it modifies the queue:

   a
      [3,4,5,9,8]

The inspect function returns the top of the queue without modification,
viewed as a BagAggregate:

   inspect a
      8

The empty? operation returns true only if there are no element on the
queue, otherwise it returns false:

   empty? a
      false

The front operation returns the front of the queue without modification:

   front a
      3

The back operation returns the back of the queue without modification:

   back a
      8

The rotate! operation moves the item at the front of the queue to the
back of the queue:

   rotate! a
      [4,5,9,8,3]

The # (length) operation:

   #a
       5

The length operation does the same thing:

   length a
       5
```

```
The less? predicate will compare the queue length to an integer:

   less?(a,9)
        true

The more? predicate will compare the queue length to an integer:

   more?(a,9)
        false

The size? operation will compare the queue length to an integer:

   size?(a,#a)
        true

and since the last computation must alwasy be true we try:

   size?(a,9)
        false

The parts function will return  the queue as a list of its elements:

   parts a
        [8,9,3,4,5]

If we have a BagAggregate of elements we can use it to construct a queue:

   bag([1,2,3,4,5])$Queue(INT)
        [1,2,3,4,5]

The empty function will construct an empty queue of a given type:

   b:=empty()$(Queue INT)
        []

and the empty? predicate allows us to find out if a queue is empty:

   empty? b
        true

The sample function returns a sample, empty queue:

   sample()$Queue(INT)
        []

We can copy a queue and it does not share storage so subsequent
modifications of the original queue will not affect the copy:

   c:=copy a
```

```
        [4,5,9,8,3]

The eq? function is only true if the lists are the same reference,
so even though c is a copy of a, they are not the same:

   eq?(a,c)
        false

However, a clearly shares a reference with itself:

   eq?(a,a)
        true

But we can compare a and c for equality:

   (a=c)@Boolean
        true

and clearly a is equal to itself:

   (a=a)@Boolean
        true

and since a and c are equal, they are clearly NOT not-equal:

   a~=c
        false

We can use the any? function to see if a predicate is true for any element:

   any?(x+->(x=4),a)
        true

or false for every element:

   any?(x+->(x=11),a)
        false

We can use the every? function to check every element satisfies a predicate:

   every?(x+->(x=11),a)
        false

We can count the elements that are equal to an argument of this type:

   count(4,a)
        1

or we can count against a boolean function:
```

```
   count(x+->(x>2),a)
        5
```

You can also map a function over every element, returning a new queue:

```
   map(x+->x+10,a)
        [14,15,19,18,13]
```

Notice that the orignal queue is unchanged:

```
   a
        [4,5,9,8,3]
```

You can use map! to map a function over every element and change
the original queue since map! is destructive:

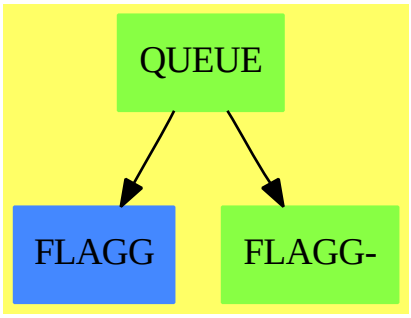
```
   map!(x+->x+10,a)
       [14,15,19,18,13]
o
```

Notice that the orignal queue has been changed:

```
   a
       [14,15,19,18,13]
```

The member function can also get the element of the queue as a list:

```
   members a
       [18,19,13,14,15]
```



and using member? we can test if the queue holds a given element:

```
   member?(14,a)
       true
```

— RadixExpansion.help —

```
========================================================================
RadixExpansion examples
========================================================================

It possible to expand numbers in general bases.

Here we expand 111 in base 5. This means
  10^2+10^1+10^0 = 4 * 5^2+2 * 5^1 + 5^0

  111::RadixExpansion(5)
    421
                              Type: RadixExpansion 5

You can expand fractions to form repeating expansions.

  (5/24)::RadixExpansion(2)
          --
    0.00110
                              Type: RadixExpansion 2

  (5/24)::RadixExpansion(3)
        --
    0.012
                              Type: RadixExpansion 3

  (5/24)::RadixExpansion(8)
        --
    0.152
```

```
                                Type: RadixExpansion 8

  (5/24)::RadixExpansion(10)
        _
    0.2083
                                Type: RadixExpansion 10
```

For bases from 11 to 36 the letters A through Z are used.

```
  (5/24)::RadixExpansion(12)
    0.26
                                Type: RadixExpansion 12

  (5/24)::RadixExpansion(16)
      _
    0.35
                                Type: RadixExpansion 16

  (5/24)::RadixExpansion(36)
    0.7I
                                Type: RadixExpansion 36
```

For bases greater than 36, the ragits are separated by blanks.

```
  (5/24)::RadixExpansion(38)
                 _____
    0 . 7 34 31 25 12
                                Type: RadixExpansion 38
```

The RadixExpansion type provides operations to obtain the individual ragits. Here is a rational number in base 8.

```
  a := (76543/210)::RadixExpansion(8)
          ____
     554.37307
                                Type: RadixExpansion 8
```

The operation wholeRagits returns a list of the ragits for the integral part of the number.

```
  w := wholeRagits a
    [5,5,4]
                                Type: List Integer
```

The operations prefixRagits and cycleRagits return lists of the initial and repeating ragits in the fractional part of the number.

```
  f0 := prefixRagits a
    [3]
                                Type: List Integer
```

```
  f1 := cycleRagits a
    [7,3,0,7]
                                Type: List Integer
```

You can construct any radix expansion by giving the whole, prefix and cycle parts. The declaration is necessary to let Axiom know the base of the ragits.

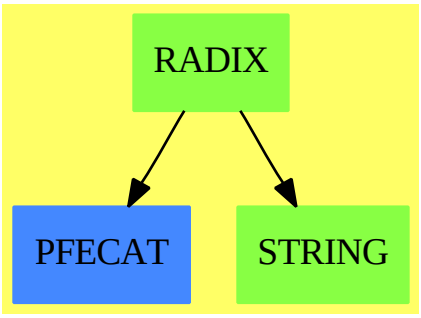
```
  u:RadixExpansion(8):=wholeRadix(w)+fractRadix(f0,f1)
          ----
    554.37307
                                Type: RadixExpansion 8
```

If there is no repeating part, then the list [0] should be used.

```
  v: RadixExpansion(12) := fractRadix([1,2,3,11], [0])
          -
    0.123B0
                                Type: RadixExpansion 12
```

If you are not interested in the repeating nature of the expansion, an infinite stream of ragits can be obtained using fractRagits.

```
  fractRagits(u)
         -------
    [3,7,3,0,7,7]
                                Type: Stream Integer
```



Of course, it's possible to recover the fraction representation:

```
  a :: Fraction(Integer)
    76543
    -----
     210
                                Type: Fraction Integer
```

— domain RADIX RadixExpansion —

```
)abbrev domain RADIX RadixExpansion
++ Author: Stephen M. Watt
++ Date Created: October 1986
++ Date Last Updated: May 15, 1991
++ Description:
++ This domain allows rational numbers to be presented as repeating
++ decimal expansions or more generally as repeating expansions in any base.

RadixExpansion(bb): Exports == Implementation where
  bb   :  Integer
  I   ==> Integer
  NNI ==> NonNegativeInteger
  OUT ==> OutputForm
  RN  ==> Fraction Integer
  ST  ==> Stream Integer
  QuoRem ==> Record(quotient: Integer, remainder: Integer)
```

```
Exports ==> QuotientFieldCategory(Integer) with
  coerce: % -> Fraction Integer
    ++ coerce(rx) converts a radix expansion to a rational number.
  fractionPart: % -> Fraction Integer
    ++ fractionPart(rx) returns the fractional part of a radix expansion.
  wholeRagits: % -> List Integer
    ++ wholeRagits(rx) returns the ragits of the integer part
    ++ of a radix expansion.
  fractRagits: % -> Stream Integer
    ++ fractRagits(rx) returns the ragits of the fractional part
    ++ of a radix expansion.
  prefixRagits: % -> List Integer
    ++ prefixRagits(rx) returns the non-cyclic part of the ragits
    ++ of the fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{prefixRagits(x)=[1,0]}.
  cycleRagits: % -> List Integer
    ++ cycleRagits(rx) returns the cyclic part of the ragits of the
    ++ fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{cycleRagits(x) = [7,1,4,2,8,5]}.
  wholeRadix: List Integer -> %
    ++ wholeRadix(l) creates an integral radix expansion from a list
    ++ of ragits.
    ++ For example, \spad{wholeRadix([1,3,4])} will return \spad{134}.
  fractRadix: (List Integer, List Integer) -> %
    ++ fractRadix(pre,cyc) creates a fractional radix expansion
    ++ from a list of prefix ragits and a list of cyclic ragits.
    ++ e.g., \spad{fractRadix([1],[6])} will return \spad{0.16666666...}.

Implementation ==> add

domain RECLOS RealClosure

The domain constructore **RealClosure** by Renaud Rioboo (University of Paris 6, France) provides the real closure of an ordered field. The implementation is based on interval arithmetic. Moreover, the design of this constructor and its related packages allows an easy use of other codings for real algebraic numbers. ordered field

The RealClosure domain is the end-user code, it provides usual arithmetics with real algebraic numbers, along with the functionalities of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute (approximate) or relative (realtivApprox).

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any

new algebraic takes precedence over older ones. In particular every cretaion function raises a new "real root". This has the effect that when you type something like sqrt(2) + sqrt(2) you have two new variables which happen to be equal. To avoid this name the expression such as in s2 := sqrt(2) ; s2 + s2

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, inparticular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Betas versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done excatly. They can thus be quite time consuming when depending on several "real roots".

========================================================================
RealClosure examples
========================================================================
```

```
The Real Closure 1.0 package provided by Renaud Rioboo consists of
different packages, categories and domains :

The package RealPolynomialUtilitiesPackage which needs a Field F and a
UnivariatePolynomialCategory domain with coefficients in F. It computes
some simple functions such as Sturm and Sylvester sequences sturmSequence,
sylvesterSequence.

The category RealRootCharacterizationCategory provides abstract
functions to work with "real roots" of univariate polynomials. These
resemble variables with some functionality needed to compute important
operations.

The category RealClosedField provides common operations available over
real closed fiels. These include finding all the roots of a univariate
polynomial, taking square (and higher) roots, ...

The domain RightOpenIntervalRootCharacterization is the main code that
provides the functionality of RealRootCharacterizationCategory for the
case of archimedean fields. Abstract roots are encoded with a left
closed right open interval containing the root together with a
defining polynomial for the root.

The RealClosure domain is the end-user code. It provides usual arithmetic
with real algebraic numbers, along with the functionality of a real closed
field. It also provides functions to approximate a real algebraic number
by an element of the base field. This approximation may either be absolute,
approximate or relative (relativeApprox).

========================================================================
CAVEATS
========================================================================

Since real algebraic expressions are stored as depending on "real
roots" which are managed like variables, there is an ordering on
these. This ordering is dynamical in the sense that any new algebraic
takes precedence over older ones. In particular every creation
function raises a new "real root". This has the effect that when you
type something like sqrt(2) + sqrt(2) you have two new variables
which happen to be equal. To avoid this name the expression such as in
s2 := sqrt(2) ; s2 + s2

Also note that computing times depend strongly on the ordering you
implicitly provide. Please provide algebraics in the order which seems
most natural to you.

========================================================================
LIMITATIONS
========================================================================
```

```
This packages uses algorithms which are published in [1] and [2] which
are based on field arithmetics, in particular for polynomial gcd
related algorithms. This can be quite slow for high degree polynomials
and subresultants methods usually work best. Beta versions of the
package try to use these techniques in a better way and work
significantly faster. These are mostly based on unpublished algorithms
and cannot be distributed. Please contact the author if you have a
particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all
computations are done exactly. They can thus be quite time consuming when
depending on several ‘‘real roots’’.

EXAMPLES

```
We shall work with the real closure of the ordered field of
rational numbers.

  Ran := RECLOS(FRAC INT)
    RealClosure Fraction Integer
                              Type: Domain

Some simple signs for square roots, these correspond to an extension
of degree 16 of the rational numbers. Examples provided by J. Abbot.

  fourSquares(a:Ran,b:Ran,c:Ran,d:Ran):Ran==sqrt(a)+sqrt(b)-sqrt(c)-sqrt(d)
                              Type: Void

These produce values very close to zero.

  squareDiff1 := fourSquares(73,548,60,586)
       +---+    +--+    +---+    +--+
    - \|586  - \|60  + \|548  + \|73

— domain RECLOS RealClosure —

```
)abbrev domain RECLOS RealClosure
++ Author: Renaud Rioboo
++ Date Created: summer 1988
++ Date Last Updated: January 2004
++ Description:
++ This domain implements the real closure of an ordered field.
++ Note:
++ The code here is generic i.e. it does not depend of the way the operations
++ are done. The two macros PME and SEG should be passed as functorial
++ arguments to the domain. It does not help much to write a category
++ since non trivial methods cannot be placed there either.
++

RealClosure(TheField): PUB == PRIV where

   TheField   : Join(OrderedRing, Field, RealConstant)

--   ThePols    : UnivariatePolynomialCategory($)
--   PME       ==> ThePols
--   TheCharDom : RealRootCharacterizationCategory($, ThePols )
--   SEG       ==> TheCharDom
-- this does not work yet

   E         ==> OutputForm
   Z         ==> Integer
   SE        ==> Symbol
   B         ==> Boolean
   SUP       ==> SparseUnivariatePolynomial($)
   N         ==> PositiveInteger
```

```
   RN        ==> Fraction Z
   LF        ==> ListFunctions2($,N)
   PME       ==> SparseUnivariatePolynomial($)
   SEG       ==> RightOpenIntervalRootCharacterization($,PME)

   PUB == Join(RealClosedField,
               FullyRetractableTo TheField,
               Algebra TheField) with

       algebraicOf :   (SEG,E) -> $
             ++ \axiom{algebraicOf(char)} is the external number

       mainCharacterization :   $ -> Union(SEG,"failed")
             ++ \axiom{mainCharacterization(x)} is the main algebraic
             ++ quantity of \axiom{x} (\axiom{SEG})

       relativeApprox :     ($,$) -> RN
             ++ \axiom{relativeApprox(n,p)} gives a relative
             ++ approximation of \axiom{n}
             ++ that has precision \axiom{p}

   PRIV == add

-- local functions

       lessAlgebraic  : $ -> $

— domain RGCHAIN RegularChain —

```
)abbrev domain RGCHAIN RegularChain
++ Author: Marc Moreno Maza
++ Date Created: 01/1999
++ Date Last Updated: 23/01/1999
++ Description:
++ A domain for regular chains (i.e. regular triangular sets) over
++ a Gcd-Domain and with a fix list of variables.
++ This is just a front-end for the \spadtype{RegularTriangularSet}
++ domain constructor.

RegularChain(R,ls): Exports == Implementation where
  R : GcdDomain
  ls: List Symbol
  V ==> OrderedVariableList ls
  E ==> IndexedExponents V
  P ==> NewSparseMultivariatePolynomial(R,V)
  TS ==> RegularTriangularSet(R,E,V,P)

  Exports ==  RegularTriangularSetCategory(R,E,V,P) with
     zeroSetSplit: (List P, Boolean, Boolean) -> List $
       ++ \spad{zeroSetSplit(lp,clos?,info?)} returns a list \spad{lts} of
       ++ regular chains such that the union of the closures of their regular
       ++ zero sets equals the affine variety associated with \spad{lp}.
       ++ Moreover, if \spad{clos?} is \spad{false} then the union of the
       ++ regular zero set of the \spad{ts} (for \spad{ts} in \spad{lts})
       ++ equals this variety.
       ++ If \spad{info?} is \spad{true} then some information is
       ++ displayed during the computations. See
       ++ zeroSetSplit from RegularTriangularSet.

  Implementation == RegularTriangularSet(R,E,V,P)

domain REGSET RegularTriangularSet

Several domain constructors implement regular triangular sets (or regular chains). Among them **RegularTriangularSet** and **SquareFreeRegularTriangularSet**. They also implement an algorithm by Marc Moreno Maza for computing triangular decompositions of polynomial systems. This method is refined in the package **LazardSetSolvingPackage** in order to produce decompositions by means of Lazard triangular sets.

====================================================================
RegularTriangularSet examples
====================================================================

The RegularTriangularSet domain constructor implements regular
triangular sets.  These particular triangular sets were introduced by
M. Kalkbrener (1991) in his PhD Thesis under the name regular chains.
Regular chains and their related concepts are presented in the paper
"On the Theories of Triangular sets" By P. Aubry, D. Lazard and
M. Moreno Maza (to appear in the Journal of Symbolic Computation).
The RegularTriangularSet constructor also provides a new method
(by the third author) for solving polynomial system by means of
regular chains.  This method has two ways of solving.  One has the
same specifications as Kalkbrener's algorithm (1991) and the other is
closer to Lazard's method (Discr. App. Math, 1991).  Moreover, this
new method removes redundant component from the decompositions when
this is not too expensive.  This is always the case with
square-free regular chains.  So if you want to obtain decompositions
without redundant components just use the SquareFreeRegularTriangularSet
domain constructor or the LazardSetSolvingPackage package constructor.
See also the LexTriangularPackage and ZeroDimensionalSolvePackage for the
case of algebraic systems with a finite number of (complex) solutions.

One of the main features of regular triangular sets is that they
naturally define towers of simple extensions of a field.  This allows
to perform with multivariate polynomials the same kind of operations
as one can do in an EuclideanDomain.

The RegularTriangularSet constructor takes four arguments.  The first
one, R, is the coefficient ring of the polynomials; it must belong to
the category GcdDomain.  The second one, E, is the exponent monoid of
the polynomials; it must belong to the category OrderedAbelianMonoidSup.
The third one, V, is the ordered set of variables; it must belong to the
category OrderedSet.  The last one is the polynomial ring; it must belong
to the category RecursivePolynomialCategory(R,E,V).  The abbreviation for
RegularTriangularSet is REGSET.  See also the constructor RegularChain
which only takes two arguments, the coefficient ring and the ordered
set of variables; in that case, polynomials are necessarily built with
the NewSparseMultivariatePolynomial domain constructor.

We shall explain now how to use the constructor REGSET and how to read
the decomposition of a polynomial system by means of regular sets.
```

```
Let us give some examples.  We start with an easy one
(Donati-Traverso) in order to understand the two ways of solving
polynomial systems provided by the REGSET constructor.

Define the coefficient ring.

  R := Integer
    Integer
                                Type: Domain

Define the list of variables,

  ls : List Symbol := [x,y,z,t]
    [x,y,z,t]
                                Type: List Symbol

and make it an ordered set;

  V := OVAR(ls)
    OrderedVariableList [x,y,z,t]
                                Type: Domain

then define the exponent monoid.

  E := IndexedExponents V
    IndexedExponents OrderedVariableList [x,y,z,t]
                                Type: Domain

Define the polynomial ring.

  P := NSMP(R, V)
    NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
                                Type: Domain

Let the variables be polynomial.

  x: P := 'x
    x
             Type: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t])
  y: P := 'y
    y
             Type: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t])

  z: P := 'z
    z
             Type: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t])
```

```
  t: P := 't
   t
            Type: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t])
```

Now call the RegularTriangularSet domain constructor.

```
  T := REGSET(R,E,V,P)
  RegularTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t],O
  rderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedV
  ariableList [x,y,z,t]))
                               Type: Domain
```

Define a polynomial system.

```
  p1 := x ** 31 - x ** 6 - x - y
      31    6
     x   - x  - x - y
            Type: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t])

  p2 := x ** 8  - z
     8
    x  - z
            Type: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t])

  p3 := x ** 10 - t
     10
    x   - t
            Type: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t])

  lp := [p1, p2, p3]
      31    6          8      10
    [x   - x  - x - y,x  - z,x   - t]
            Type: List NewSparseMultivariatePolynomial(Integer,
                                       OrderedVariableList [x,y,z,t])
```

First of all, let us solve this system in the sense of Kalkbrener.

```
  zeroSetSplit(lp)$T
       5    4      2     3     8     5    3    2   4                2
    [{z  - t ,t z y  + 2z y - t  + 2t  + t  - t ,(t  - t)x - t y - z }]
        Type: List RegularTriangularSet(Integer,
                    IndexedExponents OrderedVariableList [x,y,z,t],
                    OrderedVariableList [x,y,z,t],
                    NewSparseMultivariatePolynomial(Integer,
                        OrderedVariableList [x,y,z,t]))
```

And now in the sense of Lazard (or Wu and other authors).

```
  lts := zeroSetSplit(lp,false)$T
      5    4      2     3     8     5    3    2   4                2
   [{z  - t ,t z y  + 2z y - t  + 2t  + t  - t ,(t  - t)x - t y - z },
      3      5          2     3         2
    {t  - 1,z  - t,t z y  + 2z y + 1,z x  - t}, {t,z,y,x}]
        Type: List RegularTriangularSet(Integer,
                    IndexedExponents OrderedVariableList [x,y,z,t],
                    OrderedVariableList [x,y,z,t],
                    NewSparseMultivariatePolynomial(Integer,
                        OrderedVariableList [x,y,z,t]))
```

We can see that the first decomposition is a subset of the second.
So how can both be correct ?

Recall first that polynomials from a domain of the category
RecursivePolynomialCategory are regarded as univariate polynomials in
their main variable. For instance the second polynomial in the first
set of each decomposition has main variable y and its initial
(i.e. its leading coefficient w.r.t. its main variable) is t z.

Now let us explain how to read the second decomposition. Note that
the non-constant initials of the first set are t^4-t and t z. Then
the solutions described by this first set are the common zeros of
its polynomials that do not cancel the polynomials t^4-t and ty z.
Now the solutions of the input system lp satisfying these equations
are described by the second and the third sets of the decomposition.
Thus, in some sense, they can be considered as degenerated solutions.
The solutions given by the first set are called the generic points of
the system; they give the general form of the solutions. The first
decomposition only provides these generic points. This latter
decomposition is useful when they are many degenerated solutions
(which is sometimes hard to compute) and when one is only interested
in general informations, like the dimension of the input system.

We can get the dimensions of each component of a decomposition as follows.

```
  [coHeight(ts) for ts in lts]
    [1,0,0]
                              Type: List NonNegativeInteger
```

Thus the first set has dimension one. Indeed t can take any value,
except 0 or any third root of 1, whereas z is completely determined
from t, y is given by z and t, and finally x is given by the other
three variables. In the second and the third sets of the second
decomposition the four variables are completely determined and thus
these sets have dimension zero.

We give now the precise specifications of each decomposition. This

```
assume some mathematical knowledge.  However, for the non-expert user,
the above explanations will be sufficient to understand the other
features of the RSEGSET constructor.

The input system lp is decomposed in the sense of Kalkbrener as
finitely many regular sets T1,...,Ts such that the radical ideal
generated by lp is the intersection of the radicals of the saturated
ideals of T1,...,Ts.  In other words, the affine variety associated
with lp is the union of the closures (w.r.t. Zarisky topology) of the
regular-zeros sets of T1,...,Ts.

N. B. The prime ideals associated with the radical of the saturated
ideal of a regular triangular set have all the same dimension;
moreover these prime ideals can be given by characteristic sets with
the same main variables.  Thus a decomposition in the sense of
Kalkbrener is unmixed dimensional.  Then it can be viewed as a lazy
decomposition into prime ideals (some of these prime ideals being
merged into unmixed dimensional ideals).

Now we explain the other way of solving by means of regular triangular
sets.  The input system lp is decomposed in the sense of Lazard as
finitely many regular triangular sets T1,...,Ts such that the affine
variety associated with lp is the union of the regular-zeros sets of
T1,...,Ts.  Thus a decomposition in the sense of Lazard is also a
decomposition in the sense of Kalkbrener; the converse is false as we
have seen before.

When the input system has a finite number of solutions, both ways of
solving provide similar decompositions as we shall see with this
second example (Caprasse).

Define a polynomial system.

  f1 := y**2*z+2*x*y*t-2*x-z
                      2
    (2t y - 2)x + z y  - z
           Type: NewSparseMultivariatePolynomial(Integer,
                    OrderedVariableList [x,y,z,t])

  f2:=-x**3*z+ 4*x*y**2*z+4*x**2*y*t+2*y**3*t+4*x**2-10*y**2+4*x*z-10*y*t+2
         3              2        2              3      2
    - z x  + (4t y + 4)x  + (4z y  + 4z)x + 2t y  - 10y  - 10t y + 2
           Type: NewSparseMultivariatePolynomial(Integer,
                    OrderedVariableList [x,y,z,t])

  f3 :=  2*y*z*t+x*t**2-x-2*z
      2
    (t  - 1)x + 2t z y - 2z
           Type: NewSparseMultivariatePolynomial(Integer,
                    OrderedVariableList [x,y,z,t])
```

```
  f4:=-x*z**3+4*y*z**2*t+4*x*z*t**2+2*y*t**3+4*x*z+4*z**2-10*y*t- 10*t**2+2
        3      2               2     3            2      2
    (- z  + (4t  + 4)z)x + (4t z  + 2t  - 10t)y + 4z  - 10t  + 2
           Type: NewSparseMultivariatePolynomial(Integer,
                    OrderedVariableList [x,y,z,t])

  lf := [f1, f2, f3, f4]
                     2
   [(2t y - 2)x + z y  - z,
         3             2        2              3      2
    - z x  + (4t y + 4)x  + (4z y  + 4z)x + 2t y  - 10y  - 10t y + 2,
      2
    (t  - 1)x + 2t z y - 2z,
        3      2               2     3            2      2
    (- z  + (4t  + 4)z)x + (4t z  + 2t  - 10t)y + 4z  - 10t  + 2]
           Type: List NewSparseMultivariatePolynomial(Integer,
                           OrderedVariableList [x,y,z,t])
```

First of all, let us solve this system in the sense of Kalkbrener.

```
  zeroSetSplit(lf)$T
      2      8      6       2                 3            2
   [{t  - 1,z  - 16z  + 256z  - 256,t y - 1,(z  - 8z)x - 8z  + 16},
       2      2     2
    {3t  + 1,z  - 7t  - 1,y + t,x + z},
      8      6      2         3           2
    {t  - 10t  + 10t  - 1,z,(t  - 5t)y - 5t  + 1,x},
      2      2
    {t  + 3,z  - 4,y + t,x - z}]
      Type: List RegularTriangularSet(Integer,
                  IndexedExponents OrderedVariableList [x,y,z,t],
                  OrderedVariableList [x,y,z,t],
                  NewSparseMultivariatePolynomial(Integer,
                      OrderedVariableList [x,y,z,t]))
```

And now in the sense of Lazard (or Wu and other authors).

```
  lts2 := zeroSetSplit(lf,false)$T
      8      6      2         3           2
   [{t  - 10t  + 10t  - 1,z,(t  - 5t)y - 5t  + 1,x},
      2      8      6       2                 3            2

       Type: List RegularTriangularSet(Integer,
                  IndexedExponents OrderedVariableList [x,y,z,t],
                  OrderedVariableList [x,y,z,t],
                  NewSparseMultivariatePolynomial(Integer,
                      OrderedVariableList [x,y,z,t]))
```

```
Up to the ordering of the components, both decompositions are identical.

Let us check that each component has a finite number of solutions.

  [coHeight(ts) for ts in lts2]
    [0,0,0,0]
                        Type: List NonNegativeInteger

Let us count the degrees of each component,

  degrees := [degree(ts) for ts in lts2]
    [8,16,4,4]
                        Type: List NonNegativeInteger

and compute their sum.

  reduce(+,degrees)
    32
                        Type: PositiveInteger

We study now the options of the zeroSetSplit operation.  As we have seen
yet, there is an optional second argument which is a boolean value. If this
value is true (this is the default) then the decomposition is computed in
the sense of Kalkbrener, otherwise it is computed in the sense of Lazard.

There is a second boolean optional argument that can be used (in that
case the first optional argument must be present).  This second option
allows you to get some information during the computations.

Therefore, we need to understand a little what is going on during the
computations.  An important feature of the algorithm is that the
intermediate computations are managed in some sense like the processes
of a Unix system.  Indeed, each intermediate computation may generate
other intermediate computations and the management of all these
computations is a crucial task for the efficiency.  Thus any
intermediate computation may be suspended, killed or resumed,
depending on algebraic considerations that determine priorities for
these processes.  The goal is of course to go as fast as possible
towards the final decomposition which means to avoid as much as
possible unnecessary computations.

To follow the computations, one needs to set to true the second
argument.  Then a lot of numbers and letters are displayed.  Between a
[ and a ] one has the state of the processes at a given time.  Just
after [ one can see the number of processes.  Then each process is
represented by two numbers between < and >.  A process consists of a
list of polynomial ps and a triangular set ts; its goal is to compute
the common zeros of ps that belong to the regular-zeros set of ts.
After the processes, the number between pipes gives the total number
```

of polynomials in all the sets ps. Finally, the number between braces gives the number of components of a decomposition that are already computed. This number may decrease.

Let us take a third example (Czapor-Geddes-Wang) to see how this information is displayed.

Define a polynomial system.

```
u : R := 2
  2

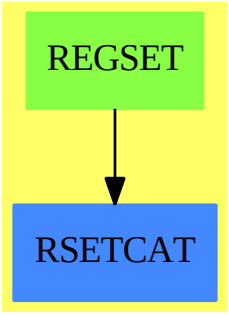
Between a sequence of processes, thus between a] and a [you can see capital letters W, G, I and lower case letters i, w. Each time a capital letter appears a non-trivial computation has be performed and its result is put in a hash-table. Each time a lower case letter appears a needed result has been found in an hash-table. The use of these hash-tables generally speed up the computations. However, on very large systems, it may happen that these hash-tables become too big to be handle by your AXIOM configuration. Then in these exceptional cases, you may prefer getting a result (even if it takes a long time) than getting nothing. Hence you need to know how to prevent the RSEGSET constructor from using these hash-tables. In that case you will be using the zeroSetSplit with five arguments. The first one is the input system lp as above. The second one is a boolean value hash? which is true iff you want to use hash-tables. The third one is boolean value clos? which is true iff you want to solve your system in the sense of Kalkbrener, the other way remaining that of Lazard. The fourth argument is boolean value info? which is true iff you want to display information during the computations. The last one is boolean value prep? which is true iff you want to use some heuristics that are performed on the input system before starting the real algorithm. The value of this flag is true when you are using zeroSetSplit with less than five arguments. Note that there is no available signature for zeroSetSplit with four arguments.



We finish this section by some remarks about both ways of solving, in the sense of Kalkbrener or in the sense of Lazard. For problems with a finite number of solutions, there are theoretically equivalent and the resulting decompositions are identical, up to the ordering of the components. However, when solving in the sense of Lazard, the

algorithm behaves differently. In that case, it becomes more incremental than in the sense of Kalkbrener. That means the polynomials of the input system are considered one after another whereas in the sense of Kalkbrener the input system is treated more globally.

This makes an important difference in positive dimension. Indeed when solving in the sense of Kalkbrener, the Primeidealkettensatz of Krull is used. That means any regular triangular containing more polynomials than the input system can be deleted. This is not possible when solving in the sense of Lazard. This explains why Kalkbrener's decompositions usually contain less components than those of Lazard. However, it may happen with some examples that the incremental process (that cannot be used when solving in the sense of Kalkbrener) provide a more efficient way of solving than the global one even if the Primeidealkettensatz is used. Thus just try both, with the various options, before concluding that you cannot solve your favorite system with zeroSetSplit. There exist more options at the development level that are not currently available in this public version.

— domain REGSET RegularTriangularSet —

```
)abbrev domain REGSET RegularTriangularSet
++ Author: Marc Moreno Maza
++ Date Created: 08/25/1998
++ Date Last Updated: 16/12/1998
++ References :
++  [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ This domain provides an implementation of regular chains.
++ Moreover, the operation zeroSetSplit is an implementation of a new
++ algorithm for solving polynomial systems by means of regular chains.

RegularTriangularSet(R,E,V,P) : Exports == Implementation where

  R : GcdDomain
  E : OrderedAbelianMonoidSup
  V : OrderedSet
  P : RecursivePolynomialCategory(R,E,V)
  N ==> NonNegativeInteger
  Z ==> Integer
  B ==> Boolean
  LP ==> List P
  PtoP ==> P -> P
  PS ==> GeneralPolynomialSet(R,E,V,P)

```

———-

— RewriteRule.help —

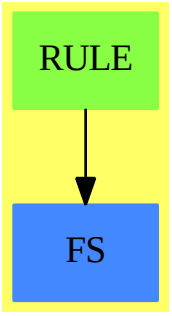
```
==========================================================================
RewriteRule examples
==========================================================================
For example:

logrule := rule log(x) + log(y) == log(x*y)
   log(y) + log(x) + %C == log(x y) + %C

f := log(sin(x)) + log(x)
   log(sin(x)) + log(x)

logrule f
   log(x sin(x))

Note that you cannot write the simple form of a rule as:



rule1 := rule a*x+b == b*x+a

as this causes an infinite loop. The pattern is properly matched
but the result also properly matches and the pattern is applied
again.

domain ROIRC RightOpenIntervalRootCharacterization

The domain RightOpenIntervalRootCharacterization is the main code that provides the functionalities of RealRootCharacterizationCategory for the case of archimedean fileds. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every cretaion function raises a new "real root". This has the effect that when you type something like sqrt(2) + sqrt(2) you have two new variables which happen to be equal. To avoid this name the expression such as in s2 := sqrt(2) ; s2 + s2

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, inparticular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Betas versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

========================================================================
RomanNumeral Examples
========================================================================

The Roman numeral package was added to Axiom in MCMLXXXVI for use in
denoting higher order derivatives.

For example, let f be a symbolic operator.

  f := operator 'f
    f
                                  Type: BasicOperator

This is the seventh derivative of f with respect to x.
  D(f x,x,7)
     (vii)
    f     (x)
                                  Type: Expression Integer

You can have integers printed as Roman numerals by declaring variables to
be of type RomanNumeral (abbreviation ROMAN).

  a := roman(1978 - 1965)
    XIII
                                  Type: RomanNumeral

This package now has a small but devoted group of followers that claim
this domain has shown its efficacy in many other contexts.  They claim
that Roman numerals are every bit as useful as ordinary integers.

In a sense, they are correct, because Roman numerals form a ring and you
can therefore construct polynomials with Roman numeral coefficients,
matrices over Roman numerals, etc..
```

```
  x : UTS(ROMAN,'x,0) := x
    x
                              Type: UnivariateTaylorSeries(RomanNumeral,x,0)
```

Was Fibonacci Italian or ROMAN?

```
  recip(1 - x - x**2)
                 2        3      4         5         6        7         8
     I + x + II x  + III x  + V x  + VIII x  + XIII x  + XXI x  + XXXIV x
   +
         9           10      11
     LV x  + LXXXIX x   + O(x  )
                    Type: Union(UnivariateTaylorSeries(RomanNumeral,x,0),...)
```

You can also construct fractions with Roman numeral numerators and denominators, as this matrix Hilberticus illustrates.

```
  m : MATRIX FRAC ROMAN
                           Type: Void

  m := matrix [ [1/(i + j) for i in 1..3] for j in 1..3]
        + I    I    I+
        |--   ---  --|
        |II   III  IV|
        |            |
        | I    I   I |
        |---  --   - |
        |III  IV   V |
        |            |
        | I    I    I|
        |--    -   --|
        +IV    V   VI+
                           Type: Matrix Fraction RomanNumeral
```

Note that the inverse of the matrix has integral ROMAN entries.

```
  inverse m
        +LXXII   - CCXL    CLXXX +
        |                        |
        |- CCXL    CM     - DCCXX|
        |                        |
        +CLXXX   - DCCXX    DC   +
                           Type: Union(Matrix Fraction RomanNumeral,...)
```

Unfortunately, the spoil-sports say that the fun stops when the numbers get big---mostly because the Romans didn't establish conventions about representing very large numbers.

```
  y := factorial 10
    3628800
```

```
                          Type: PositiveInteger
```

You work it out!

```
  roman y
  ((((I))))((((I))))((((I)))) (((I)))(((I)))(((I)))(((I)))(((I)))(((I))) ((I))(
  (I)) MMMMMMMMDCCC
                           Type: RomanNumeral
```

Issue the system command)show RomanNumeral to display the full
list of operations defined by RomanNumeral.

```
  a := roman(78)
    LXXVIII
                      Type: RomanNumeral

  b := roman(87)
    LXXXVII
                      Type: RomanNumeral

  a + b
    CLXV
                      Type: RomanNumeral

  a * b
    MMMMMMDCCLXXXVI
                      Type: RomanNumeral

  b rem a
    IX
                      Type: RomanNumeral
```

++ Date Last Updated: 29 Jun 1990
++ Description:
++ Sets of rules for the pattern matcher.
++ A ruleset is a set of pattern matching rules grouped together.

Ruleset(Base, R, F): Exports == Implementation where
  Base   : SetCategory
  R      : Join(Ring, PatternMatchable Base, OrderedSet,
                                ConvertibleTo Pattern Base)
  F      : Join(FunctionSpace R, PatternMatchable Base,
                                ConvertibleTo Pattern Base)

  RR ==> RewriteRule(Base, R, F)

  Exports ==> Join(SetCategory, Eltable(F, F)) with
    ruleset: List RR -> $
      ++ ruleset([r1,...,rn]) creates the rule set \spad{{r1,...,rn}}.
    rules  : $ -> List RR
      ++ rules(r) returns the rules contained in r.
    elt    : ($, F, PositiveInteger) -> F
      ++ elt(r,f,n) or r(f, n) applies all the rules of r to f at most n times.

  Implementation ==> add
    import ApplyRules(Base, R, F)

    Rep := Set RR

    ruleset l                        == {l}$Rep
    coerce(x:$):OutputForm           == coerce(x)$Rep
    x = y                            == x =$Rep y
    elt(x:$, f:F)                    == applyRules(rules x, f)
    elt(r:$, s:F, n:PositiveInteger) == applyRules(rules r, s, n)
    rules x                          == parts(x)$Rep

=====================================================================
ScriptFormulaFormat examples
=====================================================================

ScriptFormulaFormat provides a coercion from OutputForm} to IBM
SCRIPT/VS Mathematical Formula Format. The basic SCRIPT formula
format object consists of three parts:  a prologue, a formula part
and an epilogue.  The functions prologue, formula and epilogue
extract these parts, respectively.  The central parts of the expression
go into the formula part.  The other parts can be set (setPrologue!,
setEpilogue!) so that contain the appropriate tags for printing.
For example, the prologue and epilogue might simply contain ":df." and
":edf." so that the formula section will be printed in display math mode.

— Segment.help —

```
====================================================================
Segment examples
====================================================================

The Segment domain provides a generalized interval type.

Segments are created using the .. construct by indicating the
(included) end points.

  s := 3..10
    3..10
                              Type: Segment PositiveInteger

The first end point is called the lo and the second is called hi.
```

```
  lo s
    3
                              Type: PositiveInteger
```

These names are used even though the end points might belong to an unordered set.

```
  hi s
    10
                              Type: PositiveInteger
```

In addition to the end points, each segment has an integer "increment". An increment can be specified using the "by" construct.

```
  t := 10..3 by -2
    10..3 by - 2
                              Type: Segment PositiveInteger
```

This part can be obtained using the incr function.

```
  incr s
    1
                              Type: PositiveInteger
```

Unless otherwise specified, the increment is 1.

```
  incr t
    - 2
                              Type: Integer
```

A single value can be converted to a segment with equal end points. This happens if segments and single values are mixed in a list.

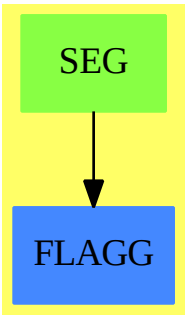
```
  l := [1..3, 5, 9, 15..11 by -1]
    [1..3,5..5,9..9,15..11 by - 1]
                               Type: List Segment PositiveInteger
```

If the underlying type is an ordered ring, it is possible to perform additional operations. The expand operation creates a list of points in a segment.

```
  expand s
    [3,4,5,6,7,8,9,10]
                               Type: List Integer
```

If k > 0, then expand(l..h by k) creates the list [l, l+k, ..., lN] where lN <= h < lN+k. If k < 0, then lN >= h > lN+k.

```
  expand t
    [10,8,6,4]
```



```
                                Type: List Integer

It is also possible to expand a list of segments.  This is equivalent
to appending lists obtained by expanding each segment individually.

  expand l
    [1,2,3,5,9,15,14,13,12,11]
                                 Type: List Integer

— SegmentBinding.help —

```
====================================================================
SegmentBinding examples
====================================================================

The SegmentBinding type is used to indicate a range for a named symbol.
```

```
First give the symbol, then an = and finally a segment of values.

  x = a..b
    x= a..b
                              Type: SegmentBinding Symbol

This is used to provide a convenient syntax for arguments to certain
operations.

  sum(i**2, i = 0..n)
      3     2
    2n  + 3n  + n
    -------------
          6
                              Type: Fraction Polynomial Integer

  draw(x**2, x = -2..2)
    TwoDimensionalViewport: "x*x"
                              Type: TwoDimensionalViewport

The left-hand side must be of type Symbol but the right-hand side can
be a segment over any type.

  sb := y = 1/2..3/2
        1    3
    y= (-)..(-)
        2    2
                              Type: SegmentBinding Fraction Integer

The left- and right-hand sides can be obtained using the variable and
segment operations.

  variable(sb)
    y
                              Type: Symbol

  segment(sb)
     1    3
    (-)..(-)
     2    2
                              Type: Segment Fraction Integer

— domain SEGBIND SegmentBinding —

```
)abbrev domain SEGBIND SegmentBinding
++ Author: Mark Botch
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain is used to provide the function argument syntax \spad{v=a..b}.
++ This is used, for example, by the top-level \spadfun{draw} functions.

SegmentBinding(S:Type): Type with
  equation: (Symbol, Segment S) -> %
      ++ equation(v,a..b) creates a segment binding value with variable
      ++ \spad{v} and segment \spad{a..b}.  Note that the interpreter parses
      ++ \spad{v=a..b} to this form.
  variable: % -> Symbol
      ++ variable(segb) returns the variable from the left hand side of
      ++ the \spadtype{SegmentBinding}.  For example, if \spad{segb} is
      ++ \spad{v=a..b}, then \spad{variable(segb)} returns \spad{v}.
  segment : % -> Segment S
      ++ segment(segb) returns the segment from the right hand side of
      ++ the \spadtype{SegmentBinding}.  For example, if \spad{segb} is
      ++ \spad{v=a..b}, then \spad{segment(segb)} returns \spad{a..b}.

  if S has SetCategory then SetCategory
 == add
```

```
  Rep := Record(var:Symbol, seg:Segment S)
  equation(x,s) == [x, s]
  variable b    == b.var
  segment b     == b.seg

  if S has SetCategory then

     b1 = b2       == variable b1 = variable b2 and segment b1 = segment b2

     coerce(b:%):OutputForm ==
       variable(b)::OutputForm = segment(b)::OutputForm

=====================================================================
Set examples
=====================================================================

The Set domain allows one to represent explicit finite sets of values.
These are similar to lists, but duplicate elements are not allowed.

Sets can be created by giving a fixed set of values ...

  s := set [x**2-1, y**2-1, z**2-1]
      2      2      2
    {x  - 1,y  - 1,z  - 1}
                          Type: Set Polynomial Integer

or by using a collect form, just as for lists.  In either case, the
set is formed from a finite collection of values.

  t := set [x**i - i+1 for i in 2..10 | prime? i]
      2      3      5      7
    {x  - 1,x  - 2,x  - 4,x  - 6}
                          Type: Set Polynomial Integer

The basic operations on sets are intersect, union, difference, and
symmetricDifference.

  i := intersect(s,t)
      2
    {x  - 1}
                          Type: Set Polynomial Integer

  u := union(s,t)
      2      3      5      7      2      2
    {x  - 1,x  - 2,x  - 4,x  - 6,y  - 1,z  - 1}
                          Type: Set Polynomial Integer

The set difference(s,t) contains those members of s which are not in t.

  difference(s,t)
      2      2
```

```
    {y  - 1,z  - 1}
                            Type: Set Polynomial Integer
```

The set symmetricDifference(s,t) contains those elements which are in s or t but not in both.

```
  symmetricDifference(s,t)
      3      5      7      2      2
    {x  - 2,x  - 4,x  - 6,y  - 1,z  - 1}
                            Type: Set Polynomial Integer
```

Set membership is tested using the member? operation.

```
  member?(y, s)
    false
                            Type: Boolean

  member?((y+1)*(y-1), s)
    true
                            Type: Boolean
```

The subset? function determines whether one set is a subset of another.

```
  subset?(i, s)
    true
                            Type: Boolean

  subset?(u, s)
    false
                            Type: Boolean
```

When the base type is finite, the absolute complement of a set is defined. This finds the set of all multiplicative generators of PrimeField 11---the integers mod 11.

```
  gs := set [g for i in 1..11 | primitive?(g := i::PF 11)]
    {2,6,7,8}
                            Type: Set PrimeField 11
```

The following values are not generators.

```
  complement gs
    {1,3,4,5,9,10,0}
                            Type: Set PrimeField 11
```

Often the members of a set are computed individually; in addition, values can be inserted or removed from a set over the course of a computation.

There are two ways to do this:

```
  a := set [i**2 for i in 1..5]
    {1,4,9,16,25}
                            Type: Set PositiveInteger
```

One is to view a set as a data structure and to apply updating operations.

```
  insert!(32, a)
    {1,4,9,16,25,32}
                            Type: Set PositiveInteger

  remove!(25, a)
    {1,4,9,16,32}
                            Type: Set PositiveInteger

  a
    {1,4,9,16,32}
                            Type: Set PositiveInteger
```

The other way is to view a set as a mathematical entity and to create new sets from old.

```
  b := b0 := set [i**2 for i in 1..5]
    {1,4,9,16,25}
                            Type: Set PositiveInteger

  b := union(b, {32})
    {1,4,9,16,25,32}
                            Type: Set PositiveInteger

  b := difference(b, {25})
    {1,4,9,16,32}
                            Type: Set PositiveInteger

  b0
    {1,4,9,16,25}
                            Type: Set PositiveInteger
```

— domain SET Set —

```
)abbrev domain SET Set
++ Author: Michael Monagan; revised by Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: May 1991
++ Description:
++ A set over a domain D models the usual mathematical notion of a finite set
++ of elements from D.
++ Sets are unordered collections of distinct elements
++ (that is, order and duplication does not matter).
++ The notation \spad{set [a,b,c]} can be used to create
++ a set and the usual operations such as union and intersection are available
++ to form new sets.
++ In our implementation, \Language{} maintains the entries in
++ sorted order.  Specifically, the parts function returns the entries
++ as a list in ascending order and
++ the extract operation returns the maximum entry.
++ Given two sets s and t where \spad{#s = m} and \spad{#t = n},
++ the complexity of\br
++ \tab{5}\spad{s = t} is \spad{O(min(n,m))}\br
```

```
++ \tab{5}\spad{s < t} is \spad{O(max(n,m))}\br
++ \tab{5}\spad{union(s,t)}, \spad{intersect(s,t)}, \spad{minus(s,t)},\br
++ \tab{10 \spad{symmetricDifference(s,t)} is \spad{O(max(n,m))}\br
++ \tab{5}\spad{member(x,t)} is \spad{O(n log n)}\br
++ \tab{5}\spad{insert(x,t)} and \spad{remove(x,t)} is \spad{O(n)}

```
)abbrev domain SETMN SetOfMIntegersInOneToN
++ Author: Manuel Bronstein
```

```
++ Date Created: 10 January 1994
++ Date Last Updated: 10 January 1994
++ Description:
++ \spadtype{SetOfMIntegersInOneToN} implements the subsets of M integers
++ in the interval \spad{[1..n]}

SetOfMIntegersInOneToN(m, n): Exports == Implementation where
  PI ==> PositiveInteger
  N  ==> NonNegativeInteger
  U  ==> Union(%, "failed")
  n,m: PI

  Exports ==> Finite with
    incrementKthElement: (%, PI) -> U
      ++ incrementKthElement(S,k) increments the k^{th} element of S,
      ++ and returns "failed" if the result is not a set of M integers
      ++ in \spad{1..n} any more.
    replaceKthElement:   (%, PI, PI) -> U
      ++ replaceKthElement(S,k,p) replaces the k^{th} element of S by p,
      ++ and returns "failed" if the result is not a set of M integers
      ++ in \spad{1..n} any more.
    elements: % -> List PI
      ++ elements(S) returns the list of the elements of S in increasing order.
    setOfMinN: List PI -> %
      ++ setOfMinN([a_1,...,a_m]) returns the set {a_1,...,a_m}.
      ++ Error if {a_1,...,a_m} is not a set of M integers in \spad{1..n}.
    enumerate: () -> Vector %
      ++ enumerate() returns a vector of all the sets of M integers in
      ++ \spad{1..n}.
    member?:   (PI, %) -> Boolean
      ++ member?(p, s) returns true is p is in s, false otherwise.
    delta: (%, PI, PI) -> N
      ++ delta(S,k,p) returns the number of elements of S which are strictly
      ++ between p and the k^{th} element of S.

=====================================================================
SequentialDifferentialVariable examples
=====================================================================

OrderlyDifferentialVariable adds a commonly used sequential ranking
to the set of derivatives of an ordered list of differential
indeterminates.  A sequential ranking is a ranking < of the
derivatives with the property that for any derivative v,
there are only a finite number of derivatives u with u < v.
This domain belongs to DifferentialVariableCategory.  It defines
weight to be just order, and it defines a sequential ranking < on
derivatives u by the lexicographic order on the pair
(variable(u), order(u)).

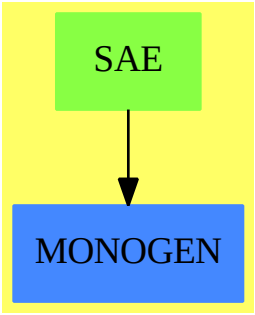
SimpleAlgebraicExtension examples
==========================================================================



Algebraic extension of a ring by a single polynomial. Domain which
represents simple algebraic extensions of arbitrary rings. The first
argument to the domain, R, is the underlying ring, the second
argument is a domain of univariate polynomials over K, while the
last argument specifies the defining minimal polynomial.

The elements of the domain are canonically represented as polynomials
of degree less than that of the minimal polynomial with coefficients
in R. The second argument is both the type of the third argument and
the underlying representation used by SAE itself.

domain SINT SingleInteger

This type represents finite (machine) precision integers which wrap around at a machine dependent value. However, **SingleInteger** has type **EntireRing** which should have no non-zero divisors. But

$$(2 * *16 : SINT) * *2 = 0$$

on a 32 bit machine. Using **SingleInteger** is a pragmatic efficiency choice. In this condition, Axiom will complain that the result is not of type FIXNUM, which is the Common Lisp type for machine integers.

=====================================================================
SingleInteger examples
=====================================================================

The SingleInteger domain is intended to provide support in Axiom
for machine integer arithmetic.  It is generally much faster than
(bignum) Integer arithmetic but suffers from a limited range of
values.  Since Axiom can be implemented on top of various dialects of
Lisp, the actual representation of small integers may not correspond
exactly to the host machines integer representation.

You can discover the minimum and maximum values in your implementation
```

```
by using min and max.

  min()$SingleInteger
    - 2147483648
                                Type: SingleInteger

  max()$SingleInteger
    2147483647
                                Type: SingleInteger

To avoid confusion with Integer, which is the default type for
integers, you usually need to work with declared variables.

  a := 1234 :: SingleInteger
    1234
                                Type: SingleInteger

or use package calling

  b := 124$SingleInteger
    124
                                Type: SingleInteger

You can add, multiply and subtract SingleInteger objects, and ask for
the greatest common divisor (gcd).

  gcd(a,b)
    2
                                Type: SingleInteger

The least common multiple (lcm) is also available.

  lcm(a,b)
    76508
                                Type: SingleInteger

Operations mulmod, addmod, submod, and invmod are similar - they provide
arithmetic modulo a given small integer.
Here is 5 * 6 mod 13.

  mulmod(5,6,13)$SingleInteger
    4
                                Type: SingleInteger

To reduce a small integer modulo a prime, use positiveRemainder.

  positiveRemainder(37,13)$SingleInteger
    11
                                Type: SingleInteger
```

```
Operations And, Or, xor, and Not provide bit level operations on small
integers.

  And(3,4)$SingleInteger
    0
                                Type: SingleInteger

Use shift(int,numToShift) to shift bits, where i is shifted left if
numToShift is positive, right if negative.

  shift(1,4)$SingleInteger
    16
                                Type: SingleInteger

  shift(31,-1)$SingleInteger
    15
                                Type: SingleInteger

Many other operations are available for small integers, including many
of those provided for Integer.

-- QSOR, QSXOR, QSLEFTSHIFT, QSADDMOD, QSDIFMOD, QSMULTMOD

SingleInteger(): Join(IntegerNumberSystem,Logic,OpenMath) with
   canonical
      ++ \spad{canonical} means that mathematical equality is
      ++ implied by data structure equality.
   canonicalsClosed
      ++ \spad{canonicalClosed} means two positives multiply to
      ++ give positive.
   noetherian
      ++ \spad{noetherian} all ideals are finitely generated
      ++ (in fact principal).

   max      : () -> %
      ++ max() returns the largest single integer.
   min      : () -> %
      ++ min() returns the smallest single integer.

   -- bit operations
   "not":   % -> %
      ++ not(n) returns the bit-by-bit logical not of the single integer n.
   "~"  :   % -> %
      ++  ~ n returns the bit-by-bit logical not of the single integer n.
   "/\": (%, %) -> %
      ++ n /\ m  returns the bit-by-bit logical and of
      ++ the single integers n and m.
   "\/" : (%, %) -> %
      ++ n \/ m  returns the bit-by-bit logical or of
      ++ the single integers n and m.
   "xor": (%, %) -> %
      ++ xor(n,m)  returns the bit-by-bit logical xor of
      ++ the single integers n and m.
   Not  : % -> %
      ++ Not(n) returns the bit-by-bit logical not of the single integer n.
   And  : (%,%) -> %
      ++ And(n,m)  returns the bit-by-bit logical and of
      ++ the single integers n and m.
   Or   : (%,%) -> %
      ++ Or(n,m)  returns the bit-by-bit logical or of
      ++ the single integers n and m.

— SparseMultivariateTaylorSeries.help —

```
=====================================================================
SparseMultivariateTaylorSeries examples
=====================================================================

Assume we have three variables which get expressed as sparse
multivariate taylor series.

  xts:=x::TaylorSeries Fraction Integer
  yts:=y::TaylorSeries Fraction Integer
  zts:=z::TaylorSeries Fraction Integer

These will cause traditional routines to expand in series form:

  t1:=sin(xts)

         1  3    1   5     1   7      1    9
    x - - x  + --- x  - ---- x  + ------ x  + O(11)
         6      120      5040      362880

We can ask for a specific coefficient, in this case, the coefficient
of the third power.

  coefficient(t1,3)

       1  3
    - - x
       6

And we can get that coefficient, expressed as a monomial.

  coefficient(t1,monomial(3,x)$IndexedExponents Symbol)

       1
    - -
       6
```

In a multivariate version we get a polynomial in x and y

```
t2:=sin(xts + yts)
```

$$
\begin{aligned}
&(y + x) + \left(-\frac{1}{6}y - \frac{1}{2}xy - \frac{1}{2}xy - \frac{1}{6}x\right) \\
&+ \\
&\left(\frac{1}{120}y + \frac{1}{24}xy + \frac{1}{12}xy + \frac{1}{12}xy + \frac{1}{24}xy + \frac{1}{120}x\right) \\
&+ \\
&\text{PAREN}\left(-\frac{1}{5040}y - \frac{1}{720}xy - \frac{1}{240}xy - \frac{1}{144}xy - \frac{1}{144}xy - \frac{1}{240}xy\right) \\
&\quad + \\
&\left(-\frac{1}{720}xy - \frac{1}{5040}x\right) \\
&+ \\
&\text{PAREN}\left(\frac{1}{362880}y + \frac{1}{40320}xy + \frac{1}{10080}xy + \frac{1}{4320}xy + \frac{1}{2880}xy\right) \\
&\quad + \\
&\left(\frac{1}{2880}xy + \frac{1}{4320}xy + \frac{1}{10080}xy + \frac{1}{40320}xy + \frac{1}{362880}x\right) \\
&+ \\
&O(11)
\end{aligned}
$$

We can ask for the third coefficient which is

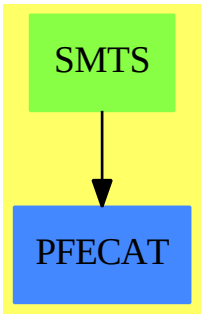
```
coefficient(t2,3)
```

$$-\frac{1}{6}y - \frac{1}{2}xy - \frac{1}{2}xy - \frac{1}{6}x$$

And we can ask for the third coefficient of that coefficient in x

```
coefficient(t2,monomial(3,x)$IndexedExponents Symbol)
```

$$-\frac{1}{6}$$



```
And we can convert that result to a polynomial

  polynomial(t2,5)

      1   5    1    4     1  2   1  3     1  3   1    2     1  4   1  2
     --- y  + -- x y  + (-- x  - -)y  + (-- x  - - x)y  + (-- x  - - x  + 1)y
     120      24         12      6       12      2         24      2
   +
      1   5   1  3
     --- x  - - x  + x
     120      6

— domain SMTS SparseMultivariateTaylorSeries —

```
)abbrev domain SMTS SparseMultivariateTaylorSeries
++ Authors: William Burge, Stephen Watt, Clifton Williamson
++ Date Created: 15 August 1988
++ Date Last Updated: 18 May 1991
++ Description:
++ This domain provides multivariate Taylor series with variables
++ from an arbitrary ordered set.  A Taylor series is represented
++ by a stream of polynomials from the polynomial domain SMP.
++ The nth element of the stream is a form of degree n.  SMTS is an
++ internal domain.

SparseMultivariateTaylorSeries(Coef,Var,SMP):_
 Exports == Implementation where
  Coef : Ring
  Var  : OrderedSet
  SMP  : PolynomialCategory(Coef,IndexedExponents Var,Var)

— SparseTable.help —

```
====================================================================
SparseTable examples
====================================================================

The SparseTable domain provides a general purpose table type with
default entries.

Here we create a table to save strings under integer keys.  The value
"Try again!" is returned if no other value has been stored for a key.

  t: SparseTable(Integer, String, "Try again!") := table()
    table()
                           Type: SparseTable(Integer,String,Try again!)

Entries can be stored in the table.

  t.3 := "Number three"
    "Number three"
                           Type: String
```

```
  t.4 := "Number four"
    "Number four"
                            Type: String
```

These values can be retrieved as usual, but if a look up fails the default entry will be returned.

```
  t.3
    "Number three"
                            Type: String

  t.2
    "Try again!"
                            Type: String
```

To see which values are explicitly stored, the keys and entries functions can be used.

```
  keys t
    [4,3]
                            Type: List Integer

  entries t
    ["Number four","Number three"]
                            Type: List String
```

If a specific table representation is required, the GeneralSparseTable constructor should be used. The domain SparseTable(K, E, dflt)} is equivalent to GeneralSparseTable(K,E,Table(K,E), dflt).

SparseUnivariateLaurentSeries examples
=====================================================================

SparseUnivariateLaurentSeries is a domain representing Laurent
series in one variable with coefficients in an arbitrary ring.  The
parameters of the type specify the coefficient ring, the power series
variable, and the center of the power series expansion.  For example,
SparseUnivariateLaurentSeries(Integer,x,3) represents Laurent
series in (x - 3) with integer coefficients.

SparseUnivariatePolynomial examples
====================================================================

This domain represents univariate polynomials over arbitrary
(not necessarily commutative) coefficient rings. The variable is
unspecified  so that the variable displays as ? on output.
If it is necessary to specify the variable name, use type
UnivariatePolynomial. The representation is sparse in the sense
that only non-zero terms are represented. Note that if the
coefficient ring is a field, this domain forms a euclidean domain.

)abbrev domain SUP SparseUnivariatePolynomial
++ Author: Dave Barton, Barry Trager
++ Description:
++ This domain represents univariate polynomials over arbitrary
++ (not necessarily commutative) coefficient rings. The variable is
++ unspecified  so that the variable displays as \spad{?} on output.
++ If it is necessary to specify the variable name,
++ use type \spadtype{UnivariatePolynomial}. The representation is sparse
++ in the sense that only non-zero terms are represented.
++ Note that if the coefficient ring is a field,
++ this domain forms a euclidean domain.

SparseUnivariatePolynomial(R:Ring): UnivariatePolynomialCategory(R) with
     outputForm : (%,OutputForm) -> OutputForm
        ++ outputForm(p,var) converts the SparseUnivariatePolynomial p to
        ++ an output form (see \spadtype{OutputForm}) printed as a polynomial in the
        ++ output form variable.
     fmecg: (%,NonNegativeInteger,R,%) -> %
        ++ fmecg(p1,e,r,p2) finds x : p1 - r * x**e * p2

domain SUPEXPR SparseUnivariatePolynomialExpressions

This domain is a hack, in some sense. What I'd really like to do - automatically - is to provide all operations supported by the coefficient domain, as long as the polynomials can be retracted to that domain, i.e., as long as they are just constants. I don't see another way to do this, unfortunately.

SparseUnivariatePuiseuxSeries examples
=====================================================================

SparseUnivariatePuiseuxSeries is a domain representing Puiseux
series in one variable with coefficients in an arbitrary ring.  The
parameters of the type specify the coefficient ring, the power series
variable, and the center of the power series expansion.  For example,
SparseUnivariatePuiseuxSeries(Integer,x,3) represents Puiseux
series in (x - 3) with Integer coefficients.

=======================================================================
SparseUnivariateTaylorSeries examples
=======================================================================

SparseUnivariateTaylorSeries is a domain representing Taylor
series in one variable with coefficients in an arbitrary ring.  The
parameters of the type specify the coefficient ring, the power series
variable, and the center of the power series expansion.  For example,
SparseUnivariateTaylorSeries(Integer,x,3) represents Taylor
series in (x - 3) with Integer coefficients.

SplitHomogeneousDirectProduct examples
==========================================================================

This type represents the finite direct or cartesian product of an
underlying ordered component type. The vectors are ordered as if
they were split into two blocks. The dim1 parameter specifies the
length of the first block. The ordering is lexicographic between
the blocks but acts like HomogeneousDirectProduct within each block.
This type is a suitable third argument for
GeneralDistributedMultivariatePolynomial.

SplittingNode examples
=====================================================================

This domain exports a modest implementation for the vertices of
splitting trees. These vertices are called here splitting nodes.
Every of these nodes store 3 informations. The first one is its
value, that is the current expression to evaluate. The second one
is its condition, that is the hypothesis under which the value has
to be evaluated. The last one is its status, that is a boolean flag
which is true iff the value is the result of its evaluation under
its condition. Two splitting vertices are equal iff they have the
sane values and the same conditions (so their status do not matter).

=====================================================================
SplittingTree examples
=====================================================================

This domain exports a modest implementation of splitting trees.
Spliiting trees are needed when the evaluation of some quantity
under some hypothesis requires to split the hypothesis into sub-cases.
For instance by adding some new hypothesis on one hand and its negation
on another hand. The computations are terminated is a splitting tree
a when status(value(a)) is true. Thus, if for the splitting tree a the
flag status(value(a)) is true, then status(value(d)) is true for any
subtree d of a. This property of splitting trees is called the termination
condition. If no vertex in a splitting tree a is equal to another,
a is said to satisfy the no-duplicates condition. The splitting
tree a will satisfy this condition if nodes are added to a by mean of
splitNodeOf! and if construct is only used to create the root of a
with no children.

      ++ \axiom{result(a)} where \axiom{ls} is the leaves list of \axiom{a}
      ++ returns \axiom{[[value(s),condition(s)]$VT for s in ls]}
      ++ if the computations are terminated in \axiom{a} else
      ++ an error is produced.
    nodeOf? : (S,%) -> B
      ++ \axiom{nodeOf?(s,a)} returns true iff some node of \axiom{a}
      ++ is equal to \axiom{s}
    subNodeOf? : (S,%,(C,C) -> B) -> B
      ++ \axiom{subNodeOf?(s,a,sub?)} returns true iff for some node
      ++ \axiom{n} in \axiom{a} we have \axiom{s = n} or
      ++ \axiom{status(n)} and \axiom{subNode?(s,n,sub?)}.
    remove : (S,%) -> %
      ++ \axiom{remove(s,a)} returns the splitting tree obtained
      ++ from a by removing every sub-tree \axiom{b} such
      ++ that \axiom{value(b)} and \axiom{s} have the same
      ++ value, condition and status.
    remove! : (S,%) -> %
      ++ \axiom{remove!(s,a)} replaces a by remove(s,a)
    splitNodeOf! : (%,%,List(S)) -> %
      ++ \axiom{splitNodeOf!(l,a,ls)} returns \axiom{a} where the children
      ++ list of \axiom{l} has been set to
      ++ \axiom{[[s]$% for s in ls | not nodeOf?(s,a)]}.
      ++ Thus, if \axiom{l} is not a node of \axiom{a}, this
      ++ latter splitting tree is unchanged.
    splitNodeOf! : (%,%,List(S),(C,C) -> B) -> %
      ++ \axiom{splitNodeOf!(l,a,ls,sub?)} returns \axiom{a} where the children
      ++ list of \axiom{l} has been set to
      ++ \axiom{[[s]$% for s in ls | not subNodeOf?(s,a,sub?)]}.
      ++ Thus, if \axiom{l} is not a node of \axiom{a}, this
      ++ latter splitting tree is unchanged.

```
====================================================================
SquareFreeRegularTriangularSet examples
====================================================================

The SquareFreeRegularTriangularSet domain constructor implements
square-free regular triangular sets.  See the RegularTriangularSet
domain constructor for general regular triangular sets.  Let T be a
regular triangular set consisting of polynomials t1, ..., tm ordered
by increasing main variables.  The regular triangular set T is
square-free if T is empty or if t1, ..., tm-1 is square-free and if the
polynomial tm is square-free as a univariate polynomial with coefficients
in the tower of simple extensions associated with t1,...,tm-1.

The main interest of square-free regular triangular sets is that their
associated towers of simple extensions are product of fields.
Consequently, the saturated ideal of a square-free regular triangular
set is radical.  This property simplifies some of the operations
related to regular triangular sets.  However, building square-free
```

regular triangular sets is generally more expensive than building general regular triangular sets.

As the RegularTriangularSet domain constructor, the SquareFreeRegularTriangularSet domain constructor also implements a method for solving polynomial systems by means of regular triangular sets. This is in fact the same method with some adaptations to take into account the fact that the computed regular chains are square-free. Note that it is also possible to pass from a decomposition into general regular triangular sets to a decomposition into square-free regular triangular sets. This conversion is used internally by the LazardSetSolvingPackage package constructor.

N.B. When solving polynomial systems with the SquareFreeRegularTriangularSet domain constructor or the LazardSetSolvingPackage package constructor, decompositions have no redundant components. See also LexTriangularPackage and ZeroDimensionalSolvePackage for the case of algebraic systems with a finite number of (complex) solutions.

We shall explain now how to use the constructor SquareFreeRegularTriangularSet.

This constructor takes four arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category GcdDomain. The second one, E, is the exponent monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. the third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The last one is the polynomial ring; it must belong to the category RecursivePolynomialCategory(R,E,V). The abbreviation for SquareFreeRegularTriangularSet} is SREGSET.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

Let us illustrate the use of this constructor with one example (Donati-Traverso). Define the coefficient ring.

```
  R := Integer
    Integer
                                  Type: Domain
```

Define the list of variables,

```
  ls : List Symbol := [x,y,z,t]
    [x,y,z,t]
                                  Type: List Symbol
```

and make it an ordered set;

```
  V := OVAR(ls)
```

```
    OrderedVariableList [x,y,z,t]
                                Type: Domain
```

then define the exponent monoid.

```
  E := IndexedExponents V
    IndexedExponents OrderedVariableList [x,y,z,t]
                                Type: Domain
```

Define the polynomial ring.

```
  P := NSMP(R, V)
    NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
                                Type: Domain
```

Let the variables be polynomial.

```
  x: P := 'x
    x
           Type: NewSparseMultivariatePolynomial(Integer,
                                 OrderedVariableList [x,y,z,t])

  y: P := 'y
    y
           Type: NewSparseMultivariatePolynomial(Integer,
                                 OrderedVariableList [x,y,z,t])

  z: P := 'z
    z
           Type: NewSparseMultivariatePolynomial(Integer,
                                 OrderedVariableList [x,y,z,t])

  t: P := 't
    t
           Type: NewSparseMultivariatePolynomial(Integer,
                                 OrderedVariableList [x,y,z,t])
```

Now call the SquareFreeRegularTriangularSet domain constructor.

```
  ST := SREGSET(R,E,V,P)
  SquareFreeRegularTriangularSet(Integer,IndexedExponents OrderedVariableList [
  x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Intege
  r,OrderedVariableList [x,y,z,t]))
                                 Type: Domain
```

Define a polynomial system.

```
  p1 := x ** 31 - x ** 6 - x - y
      31    6
     x   - x  - x - y
```

```
         Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t])

  p2 := x ** 8  - z
      8
     x  - z
         Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t])

  p3 := x ** 10 - t
      10
     x   - t
         Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t])

  lp := [p1, p2, p3]
       31    6          8      10
     [x   - x  - x - y,x  - z,x   - t]
         Type: List NewSparseMultivariatePolynomial(Integer,
                                     OrderedVariableList [x,y,z,t])
```

First of all, let us solve this system in the sense of Kalkbrener.

```
  zeroSetSplit(lp)$ST
        5    4      2     3     8     5    3    2   4                2
     [{z  - t ,t z y  + 2z y - t  + 2t  + t  - t ,(t  - t)x - t y - z }]
        Type: List SquareFreeRegularTriangularSet(Integer,
                     IndexedExponents OrderedVariableList [x,y,z,t],
                     OrderedVariableList [x,y,z,t],
                     NewSparseMultivariatePolynomial(Integer,
                        OrderedVariableList [x,y,z,t]))
```

And now in the sense of Lazard (or Wu and other authors).

```
  zeroSetSplit(lp,false)$ST
      5    4      2     3     8     5    3    2   4                2
   [{z  - t ,t z y  + 2z y - t  + 2t  + t  - t ,(t  - t)x - t y - z },
      3      5           2    2
    {t  - 1,z  - t,t y + z ,z x  - t}, {t,z,y,x}]
        Type: List SquareFreeRegularTriangularSet(Integer,
                     IndexedExponents OrderedVariableList [x,y,z,t],
                     OrderedVariableList [x,y,z,t],
                     NewSparseMultivariatePolynomial(Integer,
                        OrderedVariableList [x,y,z,t]))
```

Now to see the difference with the RegularTriangularSet domain constructor, we define:

```
  T := REGSET(R,E,V,P)
  RegularTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t],O
```

```
  rderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedV
  ariableList [x,y,z,t]))
                                Type: Domain
```

and compute:

```
  lts := zeroSetSplit(lp,false)$T
      5    4      2     3     8     5    3    2   4                2
   [{z  - t ,t z y  + 2z y - t  + 2t  + t  - t ,(t  - t)x - t y - z },
     3      5          2     3         2
    {t  - 1,z  - t,t z y  + 2z y + 1,z x  - t}, {t,z,y,x}]
          Type: List RegularTriangularSet(Integer,
                      IndexedExponents OrderedVariableList [x,y,z,t],
                      OrderedVariableList [x,y,z,t],
                      NewSparseMultivariatePolynomial(Integer,
                         OrderedVariableList [x,y,z,t]))
```

If you look at the second set in both decompositions in the sense of Lazard,
you will see that the polynomial with main variable y is not the same.

Let us understand what has happened.

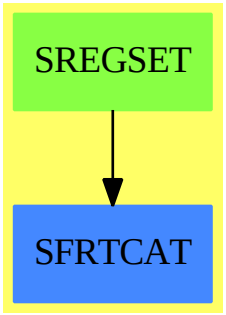
We define:

```
  ts := lts.2
           3      5          2     3         2
   (19)  {t  - 1,z  - t,t z y  + 2z y + 1,z x  - t}
        Type: RegularTriangularSet(Integer,
                IndexedExponents OrderedVariableList [x,y,z,t],
                OrderedVariableList [x,y,z,t],
                NewSparseMultivariatePolynomial(Integer,
                   OrderedVariableList [x,y,z,t]))

  pol := select(ts,'y)$T
          2     3
     t z y  + 2z y + 1
      Type: Union(NewSparseMultivariatePolynomial(Integer,
                             OrderedVariableList [x,y,z,t]),...)

  tower := collectUnder(ts,'y)$T
       3      5
     {t  - 1,z  - t}
      Type: RegularTriangularSet(Integer,
              IndexedExponents OrderedVariableList [x,y,z,t],
              OrderedVariableList [x,y,z,t],
              NewSparseMultivariatePolynomial(Integer,
                 OrderedVariableList [x,y,z,t]))

  pack := RegularTriangularSetGcdPackage(R,E,V,P,T)
  RegularTriangularSetGcdPackage(Integer,IndexedExponents OrderedVariableList [
```



```
  x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Intege
  r,OrderedVariableList [x,y,z,t]),RegularTriangularSet(Integer,IndexedExponent
  s OrderedVariableList [x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultiv
  ariatePolynomial(Integer,OrderedVariableList [x,y,z,t])))
                                        Type: Domain
```

Then we compute:

```
  toseSquareFreePart(pol,tower)$pack
                  2          3      5
    [[val= t y + z ,tower= {t  - 1,z  - t}]]
       Type: List Record(val: NewSparseMultivariatePolynomial(Integer,
                                  OrderedVariableList [x,y,z,t]),
                           tower: RegularTriangularSet(Integer,
                             IndexedExponents OrderedVariableList [x,y,z,t],
                             OrderedVariableList [x,y,z,t],
                             NewSparseMultivariatePolynomial(Integer,
                                 OrderedVariableList [x,y,z,t])))
```

```
)abbrev domain SREGSET SquareFreeRegularTriangularSet
++ Author: Marc Moreno Maza
++ Date Created: 08/25/1998
++ Date Last Updated: 16/12/1998
++ References :
++  [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ This domain provides an implementation of square-free regular chains.
++ Moreover, the operation zeroSetSplit
++ is an implementation of a new algorithm for solving polynomial systems by
++ means of regular chains.

SquareFreeRegularTriangularSet(R,E,V,P) : Exports == Implementation where

— SquareMatrix.help —

```
=====================================================================
SquareMatrix examples
=====================================================================

The top level matrix type in Axiom is Matrix, which provides basic
arithmetic and linear algebra functions.  However, since the matrices
can be of any size it is not true that any pair can be added or
multiplied.  Thus Matrix has little algebraic structure.

Sometimes you want to use matrices as coefficients for polynomials or
in other algebraic contexts.  In this case, SquareMatrix should be
```

```
used.  The domain SquareMatrix(n,R) gives the ring of n by n square
matrices over R.

Since SquareMatrix is not normally exposed at the top level, you must
expose it before it can be used.

  )set expose add constructor SquareMatrix

Once SQMATRIX has been exposed, values can be created using the
squareMatrix function.

  m := squareMatrix [ [1,-%i],[%i,4] ]
    +1   - %i+
    |        |
    +%i   4  +
                        Type: SquareMatrix(2,Complex Integer)

The usual arithmetic operations are available.

  m*m - m
    + 1   - 4%i+
    |           |
    +4%i   13  +
                        Type: SquareMatrix(2,Complex Integer)

Square matrices can be used where ring elements are required.
For example, here is a matrix with matrix entries.

  mm := squareMatrix [ [m, 1], [1-m, m**2] ]
    ++1   - %i+      +1  0+   +
    ||        |      |    |   |
    |+%i   4  +      +0  1+   |
    |                         |
    |+ 0    %i +  + 2   - 5%i+|
    ||         |  |          ||
    ++- %i  - 3+  +5%i   17  ++
                        Type: SquareMatrix(2,SquareMatrix(2,Complex Integer))

Or you can construct a polynomial with  square matrix coefficients.

  p := (x + m)**2
     2   + 2   - 2%i+    + 2   - 5%i+
    x  + |          |x + |          |
         +2%i    8  +    +5%i   17  +
                        Type: Polynomial SquareMatrix(2,Complex Integer)

This value can be converted to a square matrix with polynomial coefficients.

  p::SquareMatrix(2, ?)
    + 2                       +
```

```
    |x  + 2x + 2  - 2%i x - 5%i|
    |                          |
    |              2           |
    +2%i x + 5%i  x  + 8x + 17 +
                        Type: SquareMatrix(2,Polynomial Complex Integer)

— domain SQMATRIX SquareMatrix —

```
)abbrev domain SQMATRIX SquareMatrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{SquareMatrix} is a matrix domain of square matrices, where the
++ number of rows (= number of columns) is a parameter of the type.

SquareMatrix(ndim,R): Exports == Implementation where
  ndim : NonNegativeInteger
  R    : Ring
  Row ==> DirectProduct(ndim,R)
  Col ==> DirectProduct(ndim,R)
  MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)

  Exports ==> Join(SquareMatrixCategory(ndim,R,Row,Col),_
                   CoercibleTo Matrix R) with

    transpose: $ -> $
      ++ \spad{transpose(m)} returns the transpose of the matrix m.
    squareMatrix: Matrix R -> $
      ++ \spad{squareMatrix(m)} converts a matrix of type \spadtype{Matrix}
      ++ to a matrix of type \spadtype{SquareMatrix}.
    coerce: $ -> Matrix R
      ++ \spad{coerce(m)} converts a matrix of type \spadtype{SquareMatrix}
      ++ to a matrix of type \spadtype{Matrix}.
--  symdecomp : $ -> Record(sym:$,antisym:$)
--    ++ \spad{symdecomp(m)} decomposes the matrix m as a sum of a symmetric
--    ++ matrix \spad{m1} and an antisymmetric matrix \spad{m2}. The object
--    ++ returned is the Record \spad{[m1,m2]}
```

```
--  if R has commutative("*") then
--    minorsVect: -> Vector(Union(R,"uncomputed")) --range: 1..2**n-1
--      ++ \spad{minorsVect(m)} returns a vector of the minors of the matrix m
    if R has commutative("*") then central
      ++ the elements of the Ring R, viewed as diagonal matrices, commute
      ++ with all matrices and, indeed, are the only matrices which commute
      ++ with all matrices.
    if R has commutative("*") and R has unitsKnown then unitsKnown
      ++ the invertible matrices are simply the matrices whose determinants
      ++ are units in the Ring R.
    if R has ConvertibleTo InputForm then ConvertibleTo InputForm

  Implementation ==> Matrix R add
    minr ==> minRowIndex
    maxr ==> maxRowIndex
    minc ==> minColIndex
    maxc ==> maxColIndex
    mini ==> minIndex
    maxi ==> maxIndex

=====================================================================
Stack examples
=====================================================================

A Stack object is represented as a list ordered by last-in, first-out.
It operates like a pile of books, where the "next" book is the one
on the top of the pile.

Here we create a stack of integers from a list. Notice that the
order in the list is the order in the stack.

   a:Stack INT:= stack [1,2,3,4,5]
      [1,2,3,4,5]

We can remove the top of the stack using pop!:

   pop! a
      1

Notice that the use of pop! is destructive (destructive operations
in Axiom usually end with ! to indicate that the underylying data
```

```
structure is changed).

   a
      [2,3,4,5]

The extract! operation is another name for the pop! operation and
has the same effect. This operation treats the stack as a BagAggregate:

   extract! a
      2

and you can see that it also has destructively modified the stack:

   a
      [3,4,5]

Next we push a new element on top of the stack:

   push!(9,a)
      9
