$$\text{and } w_k = \sqrt{n}\, \hat{x}_k \bar{\hat{y}}_k$$

(the bar denoting complex conjugate).

This routine calls the same auxiliary routines as C06EAF and C06EBF to compute discrete Fourier transforms, and there are some restrictions on the value of n.

4. References

5. Parameters

1: JOB -- INTEGER Input

On entry: the computation to be performed:

$$\text{if JOB = 1, } z_k = \sum_{j=0}^{n-1} x_j y_{k-j} \quad \text{(convolution);}$$

$$\text{if JOB = 2, } w_k = \sum_{j=0}^{n-1} x_j \bar{y}_{k-j} \quad \text{(correlation).}$$

$$\sum_{j=0}^{k} j\,k+j$$

Constraint: JOB = 1 or 2.

2: X(N) -- DOUBLE PRECISION array Input/Output
On entry: the elements of one period of the vector x. If X is declared with bounds (0:N-1) in the (sub)program from which C06EKF is called, then X(j) must contain x_j, for j=0,1,...,n-1. On exit: the corresponding elements of the discrete convolution or correlation.

3: Y(N) -- DOUBLE PRECISION array Input/Output
On entry: the elements of one period of the vector y. If Y is declared with bounds (0:N-1) in the (sub)program from which C06EKF is called, then Y(j) must contain y_j, for j=0,1,...,n-1. On exit: the discrete Fourier transform of the convolution or correlation returned in the array X; the transform is stored in Hermitian form, exactly as described in the document C06EAF.

4: N -- INTEGER Input
On entry: the number of values, n, in one period of the vectors X and Y. The largest prime factor of N must not exceed 19, and the total number of prime factors of N, counting repetitions, must not exceed 20. Constraint: N > 1.

5: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
At least one of the prime factors of N is greater than 19.

IFAIL= 2
N has more than 20 prime factors.

IFAIL= 3
N <= 1.

IFAIL= 4

```
     JOB /= 1 or 2.

7. Accuracy

The results should be accurate to within a small multiple of the
machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to
n*logn, but also depends on the factorization of n. The routine
is faster than average if the only prime factors are 2, 3 or 5;
and fastest of all if n is a power of 2.

The routine is particularly slow if n has several unpaired prime
factors, i.e., if the 'square free' part of n has several
factors. For such values of n, routine C06FKF(*) is considerably
faster (but requires an additional workspace of n elements).

9. Example

This program reads in the elements of one period of two real
vectors x and y and prints their discrete convolution and
correlation (as computed by C06EKF). In realistic computations
the number of data values would be much larger.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

C06FPF computes the discrete Fourier transforms of m sequences,
each containing n real data values. This routine is designed to
be particularly efficient on vector processors.

2. Specification
```

```
      SUBROUTINE C06FPF (M, N, X, INIT, TRIG, WORK, IFAIL)
      INTEGER          M, N, IFAIL
      DOUBLE PRECISION X(M*N), TRIG(2*N), WORK(M*N)
      CHARACTER*1      INIT
```

3. Description

Given m sequences of n real data values x_j^p, for j=0,1,...,n-1; p=1,2,...,m, this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

$$\hat{z}_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j^p \times \exp\left(-i\,\frac{2\pi jk}{n}\right), \quad k=0,1,\ldots,n-1;\ p=1,2,\ldots,m.$$

(Note the scale factor $\frac{1}{\sqrt{n}}$ in this definition.)

The transformed values $\hat{z}_k^p$ are complex, but for each value of p the $\hat{z}_k^p$ form a Hermitian sequence (i.e., $\hat{z}_{n-k}^p$ is the complex conjugate of $\hat{z}_k^p$), so they are completely determined by mn real numbers (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term:

$$\hat{z}_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j^p \times \exp\left(+i\,\frac{2\pi jk}{n}\right).$$

To compute this form, this routine should be followed by a call to C06GQF to form the complex conjugates of the $\hat{z}_k^p$.

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special coding is provided for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as M, the number of transforms to be computed in parallel, increases.

4. References

[1] Brigham E O (1973) The Fast Fourier Transform. Prentice-Hall.

[2] Temperton C (1983) Fast Mixed-Radix Real Fourier Transforms. J. Comput. Phys. 52 340--350.

5. Parameters

1: M -- INTEGER Input
On entry: the number of sequences to be transformed, m.
Constraint: M >= 1.

2: N -- INTEGER Input
On entry: the number of real values in each sequence, n.
Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output
On entry: the data must be stored in X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array. In other words, if the data values of the pth sequence to be transformed are denoted by x_j^p, for j=0,1,...,n-1, then the mn elements of the array X must contain the values

$$x_0^1, x_0^2, \ldots, x_0^m, x_1^1, x_1^2, \ldots, x_1^m, \ldots, x_{n-1}^1, x_{n-1}^2, \ldots, x_{n-1}^m .$$

On exit: the m discrete Fourier transforms stored as if in a two-dimensional array of dimension (1:M,0:N-1). Each of the m transforms is stored in a row of the array in Hermitian form, overwriting the corresponding original sequence. If the n components of the discrete Fourier transform $\hat{z}_k^p$ are written as $a_k^p + ib_k^p$, then for 0<=k<=n/2, a_k^p is contained in X(p,k), and for 1<=k<=(n-1)/2, b_k^p is contained in X(p,n-k). (See also Section 2.1.2 of the

```
    Chapter Introduction.)

 4: INIT -- CHARACTER*1                                          Input
    On entry: if the trigonometric coefficients required to
    compute the transforms are to be calculated by the routine
    and stored in the array TRIG, then INIT must be set equal to
    'I' (Initial call).

    If INIT contains 'S' (Subsequent call), then the routine
    assumes that trigonometric coefficients for the specified
    value of n are supplied in the array TRIG, having been
    calculated in a previous call to one of C06FPF, C06FQF or
    C06FRF.

    If INIT contains 'R' (Restart then the routine assumes that
    trigonometric coefficients for the particular value of n are
    supplied in the array TRIG, but does not check that C06FPF,
    C06FQF or C06FRF have previously been called. This option
    allows the TRIG array to be stored in an external file, read
    in and re-used without the need for a call with INIT equal
    to 'I'. The routine carries out a simple test to check that
    the current value of n is consistent with the array TRIG.
    Constraint: INIT = 'I', 'S' or 'R'.

 5: TRIG(2*N) -- DOUBLE PRECISION array              Input/Output
    On entry: if INIT = 'S' or 'R', TRIG must contain the
    required coefficients calculated in a previous call of the
    routine. Otherwise TRIG need not be set. On exit: TRIG
    contains the required coefficients (computed by the routine
    if INIT = 'I').

 6: WORK(M*N) -- DOUBLE PRECISION array                 Workspace

 7: IFAIL -- INTEGER                                 Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.

    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
```

```
          On entry M < 1.

     IFAIL= 2
          N < 1.

     IFAIL= 3
          INIT is not one of 'I', 'S' or 'R'.

     IFAIL= 4
          INIT = 'S', but none of C06FPF, C06FQF or C06FRF has
          previously been called.

     IFAIL= 5
          INIT = 'S' or 'R', but the array TRIG and the current value
          of N are inconsistent.

     7. Accuracy

     Some indication of accuracy can be obtained by performing a
     subsequent inverse transform and comparing the results with the
     original sequence (in exact arithmetic they would be identical).

     8. Further Comments

     The time taken by the routine is approximately proportional to
     nm*logn, but also depends on the factors of n. The routine is
     fastest if the only prime factors of n are 2, 3 and 5, and is
     particularly slow if n is a large prime, or has large prime
     factors.

     9. Example

     This program reads in sequences of real data values and prints
     their discrete Fourier transforms (as computed by C06FPF). The
     Fourier transforms are expanded into full complex form using
     C06GSF and printed. Inverse transforms are then calculated by
     calling C06GQF followed by C06FQF showing that the original
     sequences are restored.

     The example program is not reproduced here. The source code for
     all example programs is distributed with the NAG Foundation
     Library software and should be available on-line.

            C06FQF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06FQF computes the discrete Fourier transforms of m Hermitian sequences, each containing n complex data values. This routine is designed to be particularly efficient on vector processors.

2. Specification

```
      SUBROUTINE C06FQF (M, N, X, INIT, TRIG, WORK, IFAIL)
      INTEGER          M, N, IFAIL
      DOUBLE PRECISION X(M*N), TRIG(2*N), WORK(M*N)
      CHARACTER*1      INIT
```

3. Description

Given m Hermitian sequences of n complex data values z_j^p, for $j=0,1,\ldots,n-1$; $p=1,2,\ldots,m$, this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

$$\hat{x}_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^p \times \exp\left(-i\,\frac{2\pi jk}{n}\right), \quad k=0,1,\ldots,n-1;\ p=1,2,\ldots,m.$$

(Note the scale factor $\frac{1}{\sqrt{n}}$ in this definition.)

The transformed values are purely real (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term

$$\hat{x}_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^p \times \exp\left(+i\,\frac{2\pi jk}{n}\right).$$

To compute this form, this routine should be preceded by a call
to C06GQF to form the complex conjugates of the $\hat{z}_j^p$.

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special code is included for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as m, the number of transforms to be computed in parallel, increases.

5. Parameters

1: M -- INTEGER Input
On entry: the number of sequences to be transformed, m.
Constraint: M >= 1.

2: N -- INTEGER Input
On entry: the number of data values in each sequence, n.
Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output
On entry: the data must be stored in X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form.
If the n data values z_j^p are written as $x_j^p + iy_j^p$, then for $0 \le j \le n/2$, x_j^p is contained in X(p,j), and for $1 \le j \le (n-1)/2$, y_j^p is contained in X(p,n-j). (See also Section 2.1.2 of the Chapter Introduction.) On exit: the components of the m discrete Fourier transforms, stored as if in a two-dimensional array of dimension (1:M,0:N-1). Each of the m transforms is stored as a row of the array, overwriting the corresponding original sequence. If the n components of the

discrete Fourier transform are denoted by $\hat{x}_k^p$, for $k=0,1,\ldots,n-1$, then the mn elements of the array X contain the values

$$\hat{x}_0^1\ \hat{x}_0^2\ \ldots\ \hat{x}_0^m\ \ \hat{x}_1^1\ \hat{x}_1^2\ \ldots\ \hat{x}_1^m\ \ \ldots\ \ \hat{x}_{n-1}^1\ \hat{x}_{n-1}^2\ \ldots\ \hat{x}_{n-1}^m .$$

4: INIT -- CHARACTER*1 Input

On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the array TRIG, then INIT must be set equal to 'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine assumes that trigonometric coefficients for the specified value of n are supplied in the array TRIG, having been calculated in a previous call to one of C06FPF, C06FQF or C06FRF.

If INIT contains 'R' (Restart), then the routine assumes that trigonometric coefficients for the particular value of N are supplied in the array TRIG, but does not check that C06FPF, C06FQF or C06FRF have previously been called. This option allows the TRIG array to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of n is compatible with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

5: TRIG(2*N) -- DOUBLE PRECISION array Input/Output

On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').

6: WORK(M*N) -- DOUBLE PRECISION array Workspace

7: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

```
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M < 1.

IFAIL= 2
     On entry N < 1.

IFAIL= 3
     On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4
     On entry INIT = 'S', but none of C06FPF, C06FQF and C06FRF
     has previously been called.

IFAIL= 5
     On entry INIT = 'S' or 'R', but the array TRIG and the
     current value of n are inconsistent.

7. Accuracy

Some indication of accuracy can be obtained by performing a
subsequent inverse transform and comparing the results with the
original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to
nm*logn, but also depends on the factors of n. The routine is
fastest if the only prime factors of n are 2, 3 and 5, and is
particularly slow if n is a large prime, or has large prime
factors.

9. Example

This program reads in sequences of real data values which are
assumed to be Hermitian sequences of complex data stored in
Hermitian form. The sequences are expanded into full complex form
using C06GSF and printed. The discrete Fourier transforms are
then computed (using C06FQF) and printed out. Inverse transforms
are then calculated by calling C06FPF followed by C06GQF showing
that the original sequences are restored.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

5. Parameters

1: M -- INTEGER Input
On entry: the number of sequences to be transformed, m.
Constraint: M >= 1.

2: N -- INTEGER Input
On entry: the number of complex values in each sequence, n.
Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output

4: Y(M,N) -- DOUBLE PRECISION array Input/Output
On entry: the real and imaginary parts of the complex data must be stored in X and Y respectively as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of each array. In other words, if the real parts of the pth sequence to be transformed are denoted by x_j^p, for j=0,1,...,n-1, then the mn elements of the array X must contain the values

$$x_0^1, x_0^2, \ldots, x_0^m, x_1^1, x_1^2, \ldots, x_1^m, \ldots, x_{n-1}^1, x_{n-1}^2, \ldots, x_{n-1}^m .$$

```
     0  0      0   1  1      1       n-1  n-1      n-1
On exit: X and Y are overwritten by the real and imaginary
parts of the complex transforms.

5:  INIT -- CHARACTER*1                                        Input
On entry: if the trigonometric coefficients required to
compute the transforms are to be calculated by the routine
and stored in the array TRIG, then INIT must be set equal to
'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine
assumes that trigonometric coefficients for the specified
value of n are supplied in the array TRIG, having been
calculated in a previous call to one of C06FPF, C06FQF or
C06FRF.

If INIT contains 'R' (Restart) then the routine assumes that
trigonometric coefficients for the particular value of n are
supplied in the array TRIG, but does not check that C06FPF,
C06FQF or C06FRF have previously been called. This option
allows the TRIG array to be stored in an external file, read
in and re-used without the need for a call with INIT equal
to 'I'. The routine carries out a simple test to check that
the current value of n is compatible with the array TRIG.
Constraint: INIT = 'I', 'S' or 'R'.

6:  TRIG(2*N) -- DOUBLE PRECISION array                Input/Output
On entry: if INIT = 'S' or 'R', TRIG must contain the
required coefficients calculated in a previous call of the
routine. Otherwise TRIG need not be set. On exit: TRIG
contains the required coefficients (computed by the routine
if INIT = 'I').

7:  WORK(2*M*N) -- DOUBLE PRECISION array                  Workspace

8:  IFAIL -- INTEGER                                       Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).
```

```
IFAIL= 1
     On entry M < 1.

IFAIL= 2
     On entry N < 1.

IFAIL= 3
     On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4
     On entry INIT = 'S', but none of C06FPF, C06FQF and C06FRF
     has previously been called.

IFAIL= 5
     On entry INIT = 'S' or 'R', but the array TRIG and the
     current value of n are inconsistent.

7. Accuracy

Some indication of accuracy can be obtained by performing a
subsequent inverse transform and comparing the results with the
original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to
nm*logn, but also depends on the factors of n. The routine is
fastest if the only prime factors of n are 2, 3 and 5, and is
particularly slow if n is a large prime, or has large prime
factors.

9. Example

This program reads in sequences of complex data values and prints
their discrete Fourier transforms (as computed by C06FRF).
Inverse transforms are then calculated using C06GCF and C06FRF
and printed out, showing that the original sequences are
restored.

      DOUBLE PRECISION X(M*N), Y(M*N), TRIGM(2*M), TRIGN(2*N),
     1                 WORK(2*M*N)
      CHARACTER*1       INIT
```

3. Description

This routine computes the two-dimensional discrete Fourier transform of a bivariate sequence of complex data values $z_{j_1 j_2}$, where $j_1 = 0,1,\ldots,m-1$, $j_2 = 0,1,\ldots,n-1$.

The discrete Fourier transform is here defined by:

$$\hat{z}_{k_1 k_2} = \frac{1}{\sqrt{mn}} \sum_{j_1=0}^{m-1} \sum_{j_2=0}^{n-1} z_{j_1 j_2} \exp\left(-2\pi i \left(\frac{j_1 k_1}{m} + \frac{j_2 k_2}{n}\right)\right),$$

where $k_1 = 0,1,\ldots,m-1$, $k_2 = 0,1,\ldots,n-1$.

(Note the scale factor of $\frac{1}{\sqrt{mn}}$ in this definition.)

To compute the inverse discrete Fourier transform, defined with $\exp(+2\pi i(\ldots))$ in the above formula instead of $\exp(-2\pi i(\ldots))$, this routine should be preceded and followed by

calls of C06GCF to form the complex conjugates of the data values and the transform.

This routine calls C06FRF to perform multiple one-dimensional discrete Fourier transforms by the fast Fourier transform (FFT) algorithm in Brigham [1]. It is designed to be particularly efficient on vector processors.

5. Parameters

1: M -- INTEGER Input
On entry: the number of rows, m, of the arrays X and Y.
Constraint: M >= 1.

2: N -- INTEGER Input
On entry: the number of columns, n, of the arrays X and Y.
Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output

4: Y(M,N) -- DOUBLE PRECISION array Input/Output
On entry: the real and imaginary parts of the complex data values must be stored in arrays X and Y respectively. If X and Y are regarded as two-dimensional arrays of dimension (0:M-1,0:N-1), then X(j ,j) and Y(j ,j) must contain the
1 2 1 2
real and imaginary parts of $z_{j_1 j_2}$. On exit: the real and imaginary parts respectively of the corresponding elements of the computed transform.

5: INIT -- CHARACTER*1 Input
On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the arrays TRIGM and TRIGN, then INIT must be set equal to 'I', (Initial call).

If INIT contains 'S', (Subsequent call), then the routine assumes that trigonometric coefficients for the specified values of m and n are supplied in the arrays TRIGM and TRIGN, having been calculated in a previous call to the

```
     routine.

     If INIT contains 'R', (Restart), then the routine assumes
     that trigonometric coefficients for the particular values of
     m and n are supplied in the arrays TRIGM and TRIGN, but does
     not check that the routine has previously been called. This
     option allows the TRIGM and TRIGN arrays to be stored in an
     external file, read in and re-used without the need for a
     call with INIT equal to 'I'. The routine carries out a
     simple test to check that the current values of m and n are
     compatible with the arrays TRIGM and TRIGN. Constraint: INIT
     = 'I', 'S' or 'R'.

 6:  TRIGM(2*M) -- DOUBLE PRECISION array            Input/Output

 7:  TRIGN(2*N) -- DOUBLE PRECISION array            Input/Output
     On entry: if INIT = 'S' or 'R',TRIGM and TRIGN must contain
     the required coefficients calculated in a previous call of
     the routine. Otherwise TRIGM and TRIGN need not be set.

     If m=n the same array may be supplied for TRIGM and TRIGN.
     On exit: TRIGM and TRIGN contain the required coefficients
     (computed by the routine if INIT = 'I').

 8:  WORK(2*M*N) -- DOUBLE PRECISION array              Workspace

 9:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M < 1.

IFAIL= 2
     On entry N < 1.

IFAIL= 3
     On entry INIT is not one of 'I', 'S' or 'R'.
```

```
IFAIL= 4
     On entry INIT = 'S', but C06FUF has not previously been
     called.

IFAIL= 5
     On entry INIT = 'S' or 'R', but at least one of the arrays
     TRIGM and TRIGN is inconsistent with the current value of M
     or N.

7. Accuracy

Some indication of accuracy can be obtained by performing a
subsequent inverse transform and comparing the results with the
original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to
mn*log(mn), but also depends on the factorization of the
individual dimensions m and n. The routine is somewhat faster
than average if their only prime factors are 2, 3 or 5; and
fastest of all if they are powers of 2.

9. Example

This program reads in a bivariate sequence of complex data values
and prints the two-dimensional Fourier transform. It then
performs an inverse transform and prints the sequence so
obtained, which may be compared to the original data values.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

             C06GBF -- NAG Foundation Library Routine Document

     Note: Before using this routine, please read the Users' Note for
     your implementation to check implementation-dependent details.
     The symbol (*) after a NAG routine name denotes a routine that is
     not included in the Foundation Library.

     1. Purpose

     C06GBF forms the complex conjugate of a Hermitian sequence of n
     data values.
```

2. Specification

```
SUBROUTINE C06GBF (X, N, IFAIL)
INTEGER          N, IFAIL
DOUBLE PRECISION X(N)
```

3. Description

This is a utility routine for use in conjunction with C06EAF, C06EBF, C06FAF(*) or C06FBF(*) to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

4. References

None.

5. Parameters

1: X(N) -- DOUBLE PRECISION array Input/Output
On entry: if the data values z_j are written as $x_j + iy_j$ and if X is declared with bounds (0:N-1) in the (sub)program from which C06GBF is called, then for $0 \le j \le n/2$, X(j) must contain x_j (=x_j), while for $n/2 < j \le n-1$, X(j) must contain $-y_{n-j}$ (=y_{n-j}). In other words, X must contain the Hermitian sequence in Hermitian form. (See also Section 2.1.2 of the Chapter Introduction). On exit: the imaginary parts y_j are negated. The real parts x_j are not referenced.

2: N -- INTEGER Input
On entry: the number of data values, n. Constraint: N >= 1.

3: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

```
     N < 1.

7. Accuracy

Exact.

8. Further Comments

The time taken by the routine is negligible.

9. Example

This program reads in a sequence of real data values, calls
C06EAF followed by C06GBF to compute their inverse discrete
Fourier transform, and prints this after expanding it from
Hermitian form into a full complex sequence.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

            INTEGER          N, IFAIL
            DOUBLE PRECISION Y(N)

     3. Description

     This is a utility routine for use in conjunction with C06ECF or
     C06FCF(*) to calculate inverse discrete Fourier transforms (see
     the Chapter Introduction).
```

```
4. References

None.

5. Parameters

 1:  Y(N) -- DOUBLE PRECISION array                  Input/Output
     On entry: if Y is declared with bounds (0:N-1) in the (sub)
     program which C06GCF is called, then Y(j) must contain the
     imaginary part of the jth data value, for 0<=j<=n-1. On
     exit: these values are negated.

 2:  N -- INTEGER                                            Input
     On entry: the number of data values, n. Constraint: N >= 1.

 3:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     N < 1.

7. Accuracy

Exact.

8. Further Comments

The time taken by the routine is negligible.

9. Example

This program reads in a sequence of complex data values and
prints their inverse discrete Fourier transform as computed by
calling C06GCF, followed by C06ECF and C06GCF again.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

C06GQF(3NAG) Foundation Library (12/10/92) C06GQF(3NAG)

C06 -- Summation of Series C06GQF
C06GQF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06GQF forms the complex conjugates of m Hermitian sequences, each containing n data values.

2. Specification

```
SUBROUTINE C06GQF (M, N, X, IFAIL)
INTEGER          M, N, IFAIL
DOUBLE PRECISION X(M*N)
```

3. Description

This is a utility routine for use in conjunction with C06FPF and C06FQF to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

4. References

None.

5. Parameters

1: M -- INTEGER Input
On entry: the number of Hermitian sequences to be conjugated, m. Constraint: M >= 1.

2: N -- INTEGER Input
On entry: the number of data values in each Hermitian sequence, n. Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output
On entry: the data must be stored in array X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form. If the n data values z_j^p are written as $x_j^p + iy_j^p$, then for $0 \le j \le n/2$, x_j^p is contained in X(p,j), and for 1<=j<=(n-

```
                    j
          p
     1)/2, y  is contained in X(p,n-j). (See also Section 2.1.2
            j
     of the Chapter Introduction.) On exit: the imaginary parts
      p                               p
     y  are negated. The real parts x  are not referenced.
      j                               j

 4:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M < 1.

IFAIL= 2
     On entry N < 1.

7. Accuracy

Exact.

8. Further Comments

None.

9. Example

This program reads in sequences of real data values which are
assumed to be Hermitian sequences of complex data stored in
Hermitian form. The sequences are expanded into full complex form
using C06GSF and printed. The sequences are then conjugated
(using C06GQF) and the conjugated sequences are expanded into
complex form using C06GSF and printed out.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

           1:  M -- INTEGER                                          Input
               On entry: the number of Hermitian sequences, m, to be
               converted into complex form. Constraint: M >= 1.

           2:  N -- INTEGER                                          Input
               On entry: the number of data values, n, in each sequence.
               Constraint: N >= 1.

           3:  X(M,N) -- DOUBLE PRECISION array                      Input
               On entry: the data must be stored in X as if in a two-
               dimensional array of dimension (1:M,0:N-1); each of the m
               sequences is stored in a row of the array in Hermitian form.
                                    p                p   p
               If the n data values z  are written as x +iy , then for
```

```
                          j                 j   j
              p
0<=j<=n/2, x  is contained in X(p,j), and for 1<=j<=(n-1)/2,
              j
 p
y  is contained in X(p,n-j). (See also Section 2.1.2 of the
 j
Chapter Introduction.)

 4:  U(M,N) -- DOUBLE PRECISION array                        Output

 5:  V(M,N) -- DOUBLE PRECISION array                        Output
     On exit: the real and imaginary parts of the m sequences of
     length n, are stored in U and V respectively, as if in two-
     dimensional arrays of dimension (1:M,0:N-1); each of the m
     sequences is stored as if in a row of each array. In other
     words, if the real parts of the pth sequence are denoted by
      p
     x , for j=0,1,...,n-1 then the mn elements of the array U
      j
     contain the values
           1  2      m   1  2      m       1    2        m
          x ,x ,...,x , x ,x ,...,x ,..., x   ,x   ,...,x
           0  0      0   1  1      1       n-1  n-1      n-1

 6:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M < 1.

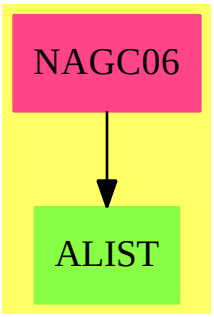
IFAIL= 2
     On entry N < 1.

7. Accuracy

Exact.
```

```
8. Further Comments

None.



9. Example

This program reads in sequences of real data values which are
assumed to be Hermitian sequences of complex data stored in
Hermitian form. The sequences are then expanded into full complex
form using C06GSF and printed.

The example program is not reproduced here. The source code for

S -- Approximations of Special Functions        Introduction -- S
                            Chapter S
                Approximations of Special Functions

1. Scope of the Chapter

This chapter is concerned with the provision of some commonly
occurring physical and mathematical functions.

2. Background to the Problems

The majority of the routines in this chapter approximate real-
valued functions of a single real argument, and the techniques
involved are described in Section 2.1. In addition the chapter
contains routines for elliptic integrals (see Section 2.2),
Bessel and Airy functions of a complex argument (see Section 2.3)
, and exponential of a complex argument.

2.1. Functions of a Single Real Argument

Most of the routines for functions of a single real argument have
been based on truncated Chebyshev expansions. This method of
approximation was adopted as a compromise between the conflicting
requirements of efficiency and ease of implementation on many
different machine ranges. For details of the reasons behind this
choice and the production and testing procedures followed in
constructing this chapter see Schonfelder [7].

Basically if the function to be approximated is f(x), then for
xis in  [a,b] an approximation of the form

                              --'
                   f(x)=g(x) >  C T (t)
                              --  r r
                              r=0

            --'
is used, ( >  denotes, according to the usual convention, a
            --
summation in which the first term is halved), where g(x) is some
suitable auxiliary function which extracts any singularities,
asymptotes and, if possible, zeros of the function in the range
in question and t=t(x) is a mapping of the general range [a,b] to
```

the specific range [-1,+1] required by the Chebyshev polynomials, $T_r(t)$. For a detailed description of the properties of the Chebyshev polynomials see Clenshaw [5] and Fox and Parker [6].

The essential property of these polynomials for the purposes of function approximation is that $T_n(t)$ oscillates between +-1 and it takes its extreme values n+1 times in the interval [-1,+1]. Therefore, provided the coefficients C_r decrease in magnitude sufficiently rapidly the error made by truncating the Chebyshev expansion after n terms is approximately given by

$$E(t)\tilde{=}C_n T_n(t)$$

That is the error oscillates between +-C_n and takes its extreme value n+1 times in the interval in question. Now this is just the condition that the approximation be a mini-max representation, one which minimizes the maximum error. By suitable choice of the interval, [a,b], the auxiliary function, g(x), and the mapping of the independent variable, t(x), it is almost always possible to obtain a Chebyshev expansion with rapid convergence and hence truncations that provide near mini-max polynomial approximations to the required function. The difference between the true mini-max polynomial and the truncated Chebyshev expansion is seldom sufficiently great to be of significance.

The evaluation of the Chebyshev expansions follows one of two methods. The first and most efficient, and hence most commonly used, works with the equivalent simple polynomial. The second method, which is used on the few occasions when the first method proves to be unstable, is based directly on the truncated Chebyshev series and uses backward recursion to evaluate the sum. For the first method, a suitably truncated Chebyshev expansion (truncation is chosen so that the error is less than the machine precision) is converted to the equivalent simple polynomial. That is we evaluate the set of coefficients b_r such that

$$y(t)= \sum_{r=0}^{n-1} b_r t^r = \sum_{r=0}^{n-1}{}' C_r T_r(t).$$

The polynomial can then be evaluated by the efficient Horner's

method of nested multiplications,

$$y(t)=(b_0+t(b_1+t(b_2+\ldots t(b_{n-2}+tb_{n-1}))))\ldots).$$

This method of evaluation results in efficient routines but for some expansions there is considerable loss of accuracy due to cancellation effects. In these cases the second method is used. It is well known that if

$$b_{n-1}=C_{n-1}$$

$$b_{n-2}=2tb_{n-1}+C_{n-2}$$

$$b_j=2tb_{j+1}-b_{j+2}+C_j,\quad j=n-3,n-4,\ldots,0$$

then

$$\sum_{r=0}^{\infty} C_r T_r(t)=-(b_0-b_2)$$

and this is always stable. This method is most efficiently implemented by using three variables cyclically and explicitly constructing the recursion.

That is,

$$\begin{aligned}
(\alpha) &= C_{n-1}\\
(\beta) &= 2t(\alpha)+C_{n-2}\\
(\gamma) &= 2t(\beta)-(\alpha)+C_{n-3}\\
(\alpha) &= 2t(\gamma)-(\beta)+C_{n-4}\\
(\beta) &= 2t(\alpha)-(\gamma)+C_{n-5}\\
&\ldots\\
&\ldots\\
(\alpha) &= 2t(\gamma)-(\beta)+C_2 \quad \text{(say)}\\
(\beta) &= 2t(\alpha)-(\gamma)+C_1\\
y(t) &= t(\beta)-(\alpha)+\tfrac{1}{2}C_0
\end{aligned}$$

2 0

The auxiliary functions used are normally functions compounded of simple polynomial (usually linear) factors extracting zeros, and the primary compiler-provided functions, sin, cos, ln, exp, sqrt, which extract singularities and/or asymptotes or in some cases basic oscillatory behaviour, leaving a smooth well-behaved function to be approximated by the Chebyshev expansion which can therefore be rapidly convergent.

The mappings of [a,b] to [-1,+1] used, range from simple linear mappings to the case when b is infinite and considerable improvement in convergence can be obtained by use of a bilinear form of mapping. Another common form of mapping is used when the function is even, that is it involves only even powers in its expansion. In this case an approximation over the whole interval

$$[-a,a] \text{ can be provided using a mapping } t=2\left(\frac{x}{a}\right)^2-1.$$

This embodies the evenness property but the expansion in t involves all powers and hence removes the necessity of working with an expansion with half its coefficients zero.

For many of the routines an analysis of the error in principle is given, viz, if E and (nabla) are the absolute errors in function and argument and (epsilon) and (delta) are the corresponding relative errors, then

$$E\tilde{}=|f'(x)|(\nabla)$$

$$E\tilde{}=|xf'(x)|(\delta)$$

$$\varepsilon\tilde{}=\left|\frac{xf'(x)}{f(x)}\right|(\delta)$$

If we ignore errors that arise in the argument of the function by propagation of data errors etc and consider only those errors that result from the fact that a real number is being represented in the computer in floating-point form with finite precision, then (delta) is bounded and this bound is independent of the magnitude of x; e.g. on an 11-digit machine

$$|(\delta)|\leq 10^{-11}.$$

(This of course implies that the absolute error (nabla)=x(delta) is also bounded but the bound is now dependent on x). However because of this the last two relations above are probably of more interest. If possible the relative error propagation is

discussed; that is the behaviour of the error amplification factor |xf'(x)/f(x)| is described, but in some cases, such as near zeros of the function which cannot be extracted explicitly, absolute error in the result is the quantity of significance and here the factor |xf'(x)| is described. In general, testing of the functions has shown that their error behaviour follows fairly well these theoretical error behaviours. In regions, where the error amplification factors are less than or of the order of one, the errors are slightly larger than the above predictions. The errors are here limited largely by the finite precision of arithmetic in the machine but (epsilon) is normally no more than a few times greater than the bound on (delta). In regions where the amplification factors are large, order of ten or greater, the theoretical analysis gives a good measure of the accuracy obtainable.

It should be noted that the definitions and notations used for the functions in this chapter are all taken from Abramowitz and Stegun [1]. Users are strongly recommended to consult this book for details before using the routines in this chapter.

2.2. Approximations to Elliptic Integrals

The functions provided here are symmetrised variants of the classic elliptic integrals. These alternative definitions have been suggested by Carlson (see [2], [3] and [4]) and he also developed the basic algorithms used in this chapter.

The standard integral of the first kind is represented by

$$R_F(x,y,z) = \frac{1}{2}\int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where x,y,z>=0 and at most one may be equal to zero.

The normalisation factor, $\frac{1}{2}$, is chosen so as to make

$$R_F(x,x,x)=1/\sqrt{x}.$$

If any two of the variables are equal, R_F degenerates into the

second function

$$R_C(x,y)=R_F(x,y,y)=\frac{1}{2}\int_0^{\infty}\frac{dt}{\sqrt{t+x}(t+y)}$$

where the argument restrictions are now x>=0 and y/=0.

This function is related to the logarithm or inverse hyperbolic functions if 0<y<x, and to the inverse circular functions if 0<=x<=y.

The integrals of the second kind are defined by

$$R_D(x,y,z)=\frac{3}{2}\int_0^{\infty}\frac{dt}{(t+x)(t+y)(t+z)^3}$$

with z>0, x>=0 and y>=0 but only one of x or y may be zero.

The function is a degenerate special case of the integral of the third kind

$$R_J(x,y,z,(\rho))=\frac{3}{2}\int_0^{\infty}\frac{dt}{(t+x)(t+y)(t+z)(t+\rho)}$$

with (rho)/=0, x,y,z>=0 with at most one equality holding. Thus $R_D(x,y,z)=R_J(x,y,z,z)$. The normalisation of both these functions is chosen so that

$$R_D(x,x,x)=R_J(x,x,x,x)=1/(x\sqrt{x})$$

The algorithms used for all these functions are based on duplication theorems. These allow a recursion system to be established which constructs a new set of arguments from the old using a combination of arithmetic and geometric means. The value of the function at the original arguments can then be simply

related to the value at the new arguments. These recursive reductions are used until the arguments differ from the mean by an amount small enough for a Taylor series about the mean to give sufficient accuracy when retaining terms of order less than six. Each step of the recurrences reduces the difference from the mean by a factor of four, and as the truncation error is of order six, the truncation error goes like $(4096)^{-n}$, where n is the number of iterations.

The above forms can be related to the more traditional canonical forms (see Abramowitz and Stegun [1], 17.2).

If we write $q=\cos^2(\phi)$, $r=1-m\sin^2(\phi)$, $s=1+n\sin^2(\phi)$, where $0<(\phi)\leq \frac{1}{2}\pi$, we have: the elliptic integral of the first kind:

$$F((\phi)|m) = \int_0^{\sin(\phi)} (1-t^2)^{-1/2} (1-mt^2)^{1-/2} dt = \sin(\phi).R_F(q,r,1);$$

the elliptic integral of the second kind:

$$E((\phi)|m) = \int_0^{\sin(\phi)} (1-t^2)^{-1/2} (1-mt^2)^{-1/2} dt = \sin(\phi).R_F(q,r,1) - \frac{1}{3}m\sin^3(\phi).R_D(q,r,1)$$

the elliptic integral of the third kind:

$$(Pi)(n;(\phi)|m) = \int_0^{\sin(\phi)} (1-t^2)^{-1/2} (1-mt^2)^{-1/2} (1+nt^2)^{2\,-1} dt = \sin(\phi).R_F(q,r,1) - \frac{1}{3}n\sin^3(\phi).R_J(q,r,1,s)$$

Also the complete elliptic integral of the first kind:

```
      (pi)/2
      /             2       -1/2
K(m)= |     (1-m.sin (theta))   d(theta)=R (0,1-m,1);

      0
```

2.3. Bessel and Airy Functions of a Complex Argument

The routines for Bessel and Airy functions of a real argument are based on Chebyshev expansions, as described in Section 2.1. The routines for functions of a complex argument, however, use different methods. These routines relate all functions to the modified Bessel functions I (z) and K (z) computed in the
                        (nu)   (nu)
right-half complex plane, including their analytic continuations. I and K are computed by different methods according to
 (nu)   (nu)
the values of zand (nu). The methods include power series, asymptotic expansions and Wronskian evaluations. The relations between functions are based on well known formulae (see Abramowitz and Stegun [1]).

3. Recommendations on Choice and Use of Routines

3.1. Elliptic Integrals

IMPORTANT ADVICE: users who encounter elliptic integrals in the course of their work are strongly recommended to look at transforming their analysis directly to one of the Carlson forms, rather than the traditional canonical Legendre forms. In general, the extra symmetry of the Carlson forms is likely to simplify the analysis, and these symmetric forms are much more stable to calculate.

The routine S21BAF for R_C is largely included as an auxiliary to the other routines for elliptic integrals. This integral essentially calculates elementary functions, e.g.

$$\ln x = (x-1).R_C\left(\frac{(1+x)^2}{4}, x\right), x>0;$$

$$\arcsin x = x.R_C\left(1-x^2, 1\right), |x|\le 1;$$

$$\operatorname{arcsinh} x = x.R_C\left(1+x^2, 1\right), \text{ etc}$$

In general this method of calculating these elementary functions is not recommended as there are usually much more efficient specific routines available in the Library. However, S21BAF may be used, for example, to compute lnx/(x-1) when x is close to 1, without the loss of significant figures that occurs when lnx and x-1 are computed separately.

3.2. Bessel and Airy Functions

For computing the Bessel functions $J_{(nu)}(x)$, $Y_{(nu)}(x)$, $I_{(nu)}(x)$ and $K_{(nu)}(x)$ where x is real and (nu)=0 or 1, special routines are provided, which are much faster than the more general

routines that allow a complex argument and arbitrary real (nu)>=0
functions and their derivatives Ai(x), Bi(x), Ai'(x), Bi'(x) for
a real argument which are much faster than the routines for
complex arguments.

S01 -- Approximations of Special Functions                 S01EAF
        S01EAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

                                              z
S01EAF evaluates the exponential function e , for complex z.

2. Specification
```

```
COMPLEX(KIND(1.0D0)) FUNCTION S01EAF (Z, IFAIL)
INTEGER                               IFAIL
COMPLEX(KIND(1.0D0))                  Z
```

3. Description

This routine evaluates the exponential function e^z, taking care to avoid machine overflow, and giving a warning if the result cannot be computed to more than half precision. The function is evaluated as $e^z = e^x(\cos y + i \sin y)$, where x and y are the real and imaginary parts respectively of z.

Since $\cos y$ and $\sin y$ are less than or equal to 1 in magnitude, it is possible that e^x may overflow although $e^x \cos y$ or $e^x \sin y$ does not. In this case the alternative formula $\text{sign}(\cos y) e^{x+\ln|\cos y|}$ is used for the real part of the result, and $\text{sign}(\sin y) e^{x+\ln|\sin y|}$ for the imaginary part. If either part of the result still overflows, a warning is returned through parameter IFAIL.

If Im z is too large, precision may be lost in the evaluation of $\sin y$ and $\cos y$. Again, a warning is returned through IFAIL.

4. References

None.

5. Parameters

1: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

```
IFAIL= 1
     The real part of the result overflows, and is set to the
     largest safe number with the correct sign. The imaginary
     part of the result is meaningful.

IFAIL= 2
     The imaginary part of the result overflows, and is set to
     the largest safe number with the correct sign. The real part
     of the result is meaningful.

IFAIL= 3
     Both real and imaginary parts of the result overflow, and
     are set to the largest safe number with the correct signs.

IFAIL= 4
     The computed result is accurate to less than half precision,
     due to the size of Im z.

IFAIL= 5
     The computed result has no precision, due to the size of Im
     z, and is set to zero.

7. Accuracy

Accuracy is limited in general only by the accuracy of the
Fortran intrinsic functions in the computation of siny, cosy and
 x
e , where x=Re z, y=Im z. As y gets larger, precision will
probably be lost due to argument reduction in the evaluation of
the sine and cosine functions, until the warning error IFAIL = 4

occurs when y gets larger than \/1/(epsilon), where (epsilon) is
the machine precision. Note that on some machines, the intrinsic
functions SIN and COS will not operate on arguments larger than

about \/1/(epsilon), and so IFAIL can never return as 4.

In the comparatively rare event that the result is computed by
                        x+ln|cosy|                x+ln|siny|
the formulae sign(cosy)e           and sign(siny)e          , a
further small loss of accuracy may be expected due to rounding
errors in the logarithmic function.

8. Further Comments

None.

9. Example
```

```
          The example program reads values of the argument z from a file,
          evaluates the function at each value of z and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

          S13 -- Approximations of Special Functions                S13AAF
                 S13AAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S13AAF returns the value of the exponential integral E (x), via
                                                                1
          the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S13AAF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          The routine calculates an approximate value for

                                    infty
                                    /     e-u
                           E (x)= |     -  du , x>0.
                            1     /     u
                                  x

          For 0<x<=4, the approximation is based on the Chebyshev expansion

                                  --                          1
                   E (x)=y(t)-lnx= > 'a T (t)-lnx , where t= -x-1.
                    1             --  r r                    2
                                  r

          For x>4,

                                  -x       -x
```

$$E_1(x) = \frac{e^x}{x} y(t) = \frac{e^x}{x} \sum_r{}' a_r T_r(t),$$

$$\text{where } t = -1.0 + 14.5/(x+3.25) = \frac{11.25-x}{3.25+x}.$$

In both cases, -1<=t<=+1.

To guard against producing underflows, if $x > x_{hi}$ the result is set directly to zero. For the value x_{hi} see the Users' Note for your implementation.

4. References

[1] Abramowitz M and Stegun I A (1965) Handbook of Mathematical Functions. Dover Publications. Ch. 26.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0.0.

2: IFAIL -- INTEGER Input/Output
Before entry, IFAIL must be assigned a value. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If (delta) and (epsilon) are the relative errors in argument and result respectively, then in principle,

```
                                  |   -x         |
                                  |  e           |
                        |(epsilon)|~=| -----*(delta)|
                                  | E (x)        |
                                  |  1           |
```

so the relative error in the argument is amplified in the result
by at least a factor $e^{-x}/E_1(x)$. The equality should hold if (delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply a result of round-off in the machine representation, it is possible that an extra figure may be lost in internal calculation and round-off.

The behaviour of this amplification factor is shown in Figure 1.

Figure 1
Please see figure in printed Reference Manual

It should be noted that, for small x, the amplification factor tends to zero and eventually the error in the result will be limited by machine precision.

For large x,

(epsilon)~x(delta)=(Delta),

the absolute error in the argument.

8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

S13 -- Approximations of Special Functions S13ACF
S13ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for

your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S13ACF returns the value of the cosine integral

$$Ci(x)=(\gamma)+\ln x+\int_0^x \frac{\cos u-1}{u}\,du, \quad x>0$$

via the routine name, where (γ) denotes Euler's constant.

2. Specification

```
      DOUBLE PRECISION FUNCTION S13ACF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for Ci(x).

For $0<x<=16$ it is based on the Chebyshev expansion

$$Ci(x)=\ln x+\sum_{r=0}{}' a_r T_r(t), \quad t=2\left(\frac{x}{16}\right)^2-1.$$

For $16<x<x_{hi}$ where the value of x_{hi} is given in the Users' Note
for your implementation,

$$Ci(x)=\frac{f(x)\sin x}{x}-\frac{g(x)\cos x}{x^2}$$

$$\text{where } f(x)=\sum_{r=0}{}' f_r T_r(t) \text{ and } g(x)=\sum_{r=0}{}' g_r T_r(t), \quad t=2\left(\frac{16}{x}\right)^2-1.$$

For $x>=x_{hi}$, Ci(x)=0 to within the accuracy possible (see Section
7).

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0.0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If E and (epsilon) are the absolute and relative errors in the result and (delta) is the relative error in the argument then in principle these are related by

$$|E| \simeq |(\mathrm{delta})\cos x| \text{ and } |(\mathrm{epsilon})| \simeq \left|\frac{(\mathrm{delta})\cos x}{\mathrm{Ci}(x)}\right|.$$

That is accuracy will be limited by machine precision near the origin and near the zeros of cosx, but near the zeros of Ci(x) only absolute accuracy can be maintained.

The behaviour of this amplification is shown in Figure 1.

Figure 1
Please see figure in printed Reference Manual

sinx

```
For large values of x, Ci(x)~ ---- therefore
                                x
(epsilon)~(delta)xcotx and since (delta) is limited by the finite
precision of the machine it becomes impossible to return results
which have any relative accuracy. That is, when x>=1/(delta) we
have that |Ci(x)|<=1/x~E and hence is not significantly different
from zero.

Hence x   is chosen such that for values of x>=x  , Ci(x) in
       hi                                      hi
principle would have values less than the machine precision and
so is essentially zero.

8. Further Comments

For details of the time taken by the routine see the Users' Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S13 -- Approximations of Special Functions                S13ADF
        S13ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S13ADF returns the value of the sine integral

                                x
                                / sinu
                      Si(x)= | ----du,
                                /  u
                                0

via the routine name.

2. Specification
```

```
      DOUBLE PRECISION FUNCTION S13ADF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for Si(x).

For |x|<=16.0 it is based on the Chebyshev expansion

$$Si(x) = x \sum_{r=0}^{\prime\prime} a_r T_r(t), \quad t = 2\left(\frac{x}{16}\right)^2 - 1.$$

For $16 < |x| < x_{hi}$, where x_{hi} is an implementation dependent number,

$$Si(x) = \mathrm{sign}(x)\left\{\frac{\pi}{2} - \frac{f(x)\cos x}{x} - \frac{g(x)\sin x}{x^2}\right\}$$

where $f(x) = \sum_{r=0}^{\prime\prime} f_r T_r(t)$ and $g(x) = \sum_{r=0}^{\prime\prime} g_r T_r(t)$, $t = 2\left(\frac{16}{x}\right)^2 - 1$.

For $|x| \geq x_{hi}$, $Si(x) = -\frac{1}{2}(\pi)\mathrm{sign}x$ to within machine precision.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

```
6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL
has been included for consistency with other routines in this
chapter.

7. Accuracy

If (delta) and (epsilon) are the relative errors in the argument
and result, respectively, then in principle

                                | (delta)sinx|
                 |(epsilon)|~=| -----------|.
                                |    Si(x)   |

The equality may hold if (delta) is greater than the machine
precision ((delta) due to data errors etc) but if (delta) is
simply due to round-off in the machine representation, then since
the factor relating (delta) to (epsilon) is always less than one,
the accuracy will be limited by machine precision.

8. Further Comments

For details of the time taken by the routine see the Users' Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S14 -- Approximations of Special Functions                 S14AAF
        S14AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S14AAF returns the value of the Gamma function (Gamma)(x), via
the routine name.
```

2. Specification

```
DOUBLE PRECISION FUNCTION S14AAF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Gamma function (Gamma)(x). The routine is based on the Chebyshev expansion:

$$(\text{Gamma})(1+u) = \sum_{r=0}^{--'} a_r T_r(t), \quad \text{where } 0 \le u < 1,\ t = 2u-1,$$

and uses the property (Gamma)(1+x)=x(Gamma)(x). If x=N+1+u where N is integral and 0<=u<1 then it follows that:

for N>0 $(\text{Gamma})(x) = (x-1)(x-2)\ldots(x-N)(\text{Gamma})(1+u)$,

for N=0 $(\text{Gamma})(x) = (\text{Gamma})(1+u)$,

for N<0 $$(\text{Gamma})(x) = \frac{(\text{Gamma})(1+u)}{x(x+1)(x+2)\ldots(x-N-1)}.$$

There are four possible failures for this routine:

(i) if x is too large, there is a danger of overflow since (Gamma)(x) could become too large to be represented in the machine;

(ii) if x is too large and negative, there is a danger of underflow;

(iii) if x is equal to a negative integer, (Gamma)(x) would overflow since it has poles at such points;

(iv) if x is too near zero, there is again the danger of overflow on some machines. For small x, $(\text{Gamma})(x) \tilde{=} \frac{1}{x}$, and on some machines there exists a range of non-zero but small values of x for which 1/x is larger than the greatest representable value.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X must not be a negative integer.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The argument is too large. On soft failure the routine returns the approximate value of (Gamma)(x) at the nearest valid argument.

IFAIL= 2
The argument is too large and negative. On soft failure the routine returns zero.

IFAIL= 3
The argument is too close to zero. On soft failure the routine returns the approximate value of (Gamma)(x) at the nearest valid argument.

IFAIL= 4
The argument is a negative integer, at which value (Gamma)(x) is infinite. On soft failure the routine returns a large positive value.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and the result respectively. If (delta) is somewhat larger than the machine precision (i.e., is due to data errors etc), then (epsilon) and (delta) are approximately related by:

(epsilon)~=|x(Psi)(x)|(delta)

(provided (epsilon) is also greater than the representation

error). Here (Psi)(x) is the digamma function $\frac{(\text{Gamma})'(x)}{(\text{Gamma})(x)}$.

Figure 1 shows the behaviour of the error amplification factor |x(Psi)(x)|.

Figure 1
Please see figure in printed Reference Manual

If (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

There is clearly a severe, but unavoidable, loss of accuracy for arguments close to the poles of (Gamma)(x) at negative integers. However relative accuracy is preserved near the pole at x=0 right up to the point of failure arising from the danger of overflow.

Also accuracy will necessarily be lost as x becomes large since in this region

(epsilon)~=(delta)xlnx.

However since (Gamma)(x) increases rapidly with x, the routine must fail due to the danger of overflow before this loss of accuracy is too great. (e.g. for x=20, the amplification factor ~= 60.)

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S14 -- Approximations of Special Functions S14ABF
S14ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details.

```
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S14ABF returns a value for the logarithm of the Gamma function,
ln(Gamma)(x), via the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S14ABF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to ln(Gamma)(x). It is
based on two Chebyshev expansions.

For 0<x<=x     , ln(Gamma)(x)=-lnx to within machine accuracy.
          small

For x     <x<=15.0, the recursive relation
     small
(Gamma)(1+x)=x(Gamma)(x) is used to reduce the calculation to one
involving (Gamma)(1+u), 0<=u<1 which is evaluated as:

                              --'
                 (Gamma)(1+u)= >   a T (t),  t=2u-1.
                              --   r r
                              r=0

Once (Gamma)(x) has been calculated, the required result is
produced by taking the logarithm.

For 15.0<x<=x   ,
             big

                                  1        1
              ln(Gamma)(x)=(x- -)lnx-x+ -ln2(pi)+y(x)/x
                                  2        2
                                     2
              --'              ( 15)
where y(x)= >   b T (t), t=2( --) -1.
              --   r r        ( x )
              r=0

For x   <x<=x     the term y(x)/x is negligible and so its
     big     vbig
calculation is omitted.
```

```
For x>x     there is a danger of setting overflow so the routine
       vbig
must fail.

For x<=0.0 the function is not defined and the routine fails.

Note: x      is calculated so that if x<x     , (Gamma)(x)=1/x to
       small                             small
within machine accuracy. x    is calculated so that if x>x   ,
                         big                               big

                                 1        1
              ln(Gamma)(x)=(x- -)lnx-x+ -ln2(pi)
                                 2        2

to within machine accuracy. x     is calculated so that
                             vbig
ln(Gamma)(x    ) is close to the value returned by X02ALF(*).
          vbig

4. References

[1]   Abramowitz M and Stegun I A (1968) Handbook of Mathematical
      Functions. Dover Publications.

5. Parameters

 1:  X -- DOUBLE PRECISION                                    Input
     On entry: the argument x of the function. Constraint: X > 0.
     0.

 2:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     X <= 0.0, the function is undefined. On soft failure, the
     routine returns zero.

IFAIL= 2
     X is too large, the function would overflow. On soft
```

failure, the routine returns the value of the function at
the largest permissible argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and result respectively, and E be the absolute error in the
result.

If (delta) is somewhat larger than the relative machine
precision, then

$$E\tilde{}=|x*(\mathrm{Psi})(x)|(\mathrm{delta}) \text{ and } (\mathrm{epsilon})\tilde{}=\left|\frac{x*(\mathrm{Psi})(x)}{\ln(\mathrm{Gamma})(x)}\right|(\mathrm{delta})$$

where (Psi)(x) is the digamma function $\frac{(\mathrm{Gamma})'(x)}{(\mathrm{Gamma})(x)}$. Figure 1 and
Figure 2 show the behaviour of these error amplification factors.

Figure 1
Please see figure in printed Reference Manual

Figure 2
Please see figure in printed Reference Manual

These show that relative error can be controlled, since except
near x=1 or 2 relative error is attenuated by the function or at
least is not greatly amplified.

$$\text{For large x, } (\mathrm{epsilon})\tilde{}=\left(1+\frac{1}{\ln x}\right)(\mathrm{delta}) \text{ and for small x,}$$

$$(\mathrm{epsilon})\tilde{}=\frac{1}{\ln x}(\mathrm{delta}).$$

The function ln(Gamma)(x) has zeros at x=1 and 2 and hence
relative accuracy is not maintainable near those points. However
absolute accuracy can still be provided near those zeros as is
shown above.

If however, (delta) is of the order of the machine precision,
then rounding errors in the routine's internal arithmetic may
result in errors which are slightly larger than those predicted
by the equalities. It should be noted that even in areas where
strong attenuation of errors is predicted the relative precision
is bounded by the effective machine precision.

```
          8. Further Comments

          For details of the time taken by the routine see the Users' Note
          for your implementation.

          9. Example

          The example program reads values of the argument x from a file,
          evaluates the function at each value of x and prints the results.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

          S14 -- Approximations of Special Functions                S14BAF
                  S14BAF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S14BAF computes values for the incomplete gamma functions P(a,x)
          and Q(a,x).

          2. Specification

                 SUBROUTINE S14BAF (A, X, TOL, P, Q, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION A, X, TOL, P, Q

          3. Description

          This subroutine evaluates the incomplete gamma functions in the
          normalised form

                                          x
                                1         /  a-1 -t
                     P(a,x)= ---------- | t   e  dt,
                             (Gamma)(a) /
                                        0

                                       infty
                                1       /     a-1 -t
                     Q(a,x)= ---------- |    t   e  dt,
```

```
                        (Gamma)(a) /
                                   x
```

with x>=0 and a>0, to a user-specified accuracy. With this normalisation, P(a,x)+Q(a,x)=1.

Several methods are used to evaluate the functions depending on the arguments a and x, the methods including Taylor expansion for P(a,x), Legendre's continued fraction for Q(a,x), and power series for Q(a,x). When both a and x are large, and a~=x, the uniform asymptotic expansion of Temme [3] is employed for greater efficiency - specifically, this expansion is used when a>=20 and 0.7a<=x<=1.4a.

Once either of P or Q is computed, the other is obtained by subtraction from 1. In order to avoid loss of relative precision in this subtraction, the smaller of P and Q is computed first.

This routine is derived from subroutine GAM in Gautschi [2].

[2] Gautschi W (1979) Algorithm 542: Incomplete Gamma Functions. ACM Trans. Math. Softw. 5 482--489.

[3] Temme N M (1987) On the Computation of the Incomplete Gamma Functions for Large Values of the Parameters. Algorithms for Approximation. (ed J C Mason and M G Cox) Oxford University Press.

5. Parameters

1: A -- DOUBLE PRECISION Input
On entry: the argument a of the functions. Constraint: A > 0.0.

2: X -- DOUBLE PRECISION Input
On entry: the argument x of the functions. Constraint: X >= 0.0.

3: TOL -- DOUBLE PRECISION Input
On entry: the relative accuracy required by the user in the results. If S14BAF is entered with TOL greater than 1.0 or less than machine precision, then the value of machine precision is used instead.

4: P -- DOUBLE PRECISION Output

```
 5:  Q -- DOUBLE PRECISION                                  Output
     On exit: the values of the functions P(a,x) and Q(a,x)
     respectively.

 6:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry A <= 0.0.

IFAIL= 2
     On entry X < 0.0.

IFAIL= 3
     Convergence of the Taylor series or Legendre continued
     fraction fails within 600 iterations. This error is
     extremely unlikely to occur; if it does, contact NAG.

7. Accuracy

There are rare occasions when the relative accuracy attained is
somewhat less than that specified by parameter TOL. However, the
error should never exceed more than one or two decimal places.
Note also that there is a limit of 18 decimal places on the
achievable accuracy, because constants in the routine are given
to this precision.

8. Further Comments

The time taken for a call of S14BAF depends on the precision
requested through TOL, and also varies slightly with the input
arguments a and x.

9. Example

The example program reads values of the argument a and x from a
file, evaluates the function and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
```

Library software and should be available on-line.

%%

S15 -- Approximations of Special Functions S15ADF
S15ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S15ADF returns the value of the complementary error function, erfcx, via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S15ADF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

The routine calculates an approximate value for the complement of the error function

$$\operatorname{erfc} x = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-u^2} du = 1 - \operatorname{erf} x.$$

For x>=0, it is based on the Chebyshev expansion

$$\operatorname{erfc} x = e^{-x^2} y(x),$$

$$\text{where } y(x) = \sum_{r=0}^{\prime\prime} a_r T_r(t) \text{ and } t=(x-3.75)/(x+3.75),\ -1 \le t \le +1.$$

For $x \ge x_{hi}$, where there is a danger of setting underflow, the result is returned as zero.

```
                   2
                 -x
For x<0, erfc x=2-e   y(|x|).

For x<x   <0, the result is returned as 2.0 which is correct to
       low
within machine precision. The values of x   and x    are given in
                                         hi      low
the Users' Note for your implementation.

4. References

[1]   Abramowitz M and Stegun I A (1968) Handbook of Mathematical
      Functions. Dover Publications.

5. Parameters

 1:  X -- DOUBLE PRECISION                                    Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL
has been included for consistency with other routines in this
chapter.

7. Accuracy

If (delta) and (epsilon) are relative errors in the argument and
result, respectively, then in principle

                           |         2          |
                           |       -x           |
                           |    2xe             |
             |(epsilon)|~=| ------------(delta)|.
                           |                    |

                           | \/(pi)erfc x       |

That is, the relative error in the argument, x, is amplified by a
               2
             -x
```

$$\text{factor } \frac{2xe}{\sqrt{\pi}\,\mathrm{erfc}\,x} \text{ in the result.}$$

The behaviour of this factor is shown in Figure 1.

Figure 1

Please see figure in printed Reference Manual

It should be noted that near x=0 this factor behaves as $\frac{2x}{\sqrt{\pi}}$ and hence the accuracy is largely determined by the machine precision. Also for large negative x, where the factor is $\tilde{} \frac{xe^{-x^2}}{\sqrt{\pi}}$, accuracy is mainly limited by machine precision.

However, for large positive x, the factor becomes $\tilde{}2x^2$ and to an extent relative accuracy is necessarily lost. The absolute accuracy E is given by

$$E\tilde{} = \frac{2xe^{-x^2}}{\sqrt{\pi}}(\mathrm{delta})$$

so absolute accuracy is guaranteed for all x.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file,

```
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S15 -- Approximations of Special Functions                 S15AEF
        S15AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S15AEF returns the value of the error function erfx, via the
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S15AEF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

Evaluates the error function,

                          2
                       x -t
                 2     /
     erf x =  ------ |e   dt.
                     /
              \/(pi) 0

For |x|<=2,
                 --'                    1 2
      erf x = x >   a T (t), where t= -x -1.
                 --   r r               2
                 r=0

For 2<|x|<x   ,
           hi
                    {        2              }
                    {      -x               }
                    {     e       --         }           x-7
      erf x = signx{1- ---------- >  'b T (t)}, where t= ---.
```

```
                  {             --   r r   }           x+3
                  {   |x|\/(pi) r=0        }
```

For $|x| \geq x_{hi}$,

$$\operatorname{erf} x = \operatorname{signx}.$$

x_{hi} is the value above which erf x=+-1 within machine precision.
Its value is given in the Users' Note for your implementation.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

On a machine with approximately 11 significant figures the routine agrees with available tables to 10 figures and consistency checking with S15ADF of the relation

$$\operatorname{erf} x + \operatorname{erfc} x = 1.0$$

shows errors in at worst the 11th figure.

8. Further Comments

None.

9. Example

```
The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S17 -- Approximations of Special Functions                  S17ACF
        S17ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17ACF returns the value of the Bessel Function Y (x), via the
                                                  0
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S17ACF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Bessel Function of
the second kind Y (x).
                0

Note: Y (x) is undefined for x<=0 and the routine will fail for
       0
such arguments.

The routine is based on four Chebyshev expansions:

For 0<x<=8,
                                                          2
            2      --'          --'                  ( x)
    Y (x)= ----lnx >   a T (t)+ >   b T (t), with t=2( -) -1,
     0     (pi)    --   r r     --   r r             ( 8)
                   r=0          r=0

For x>8,
```

$$Y_0(x) = \sqrt{\frac{2}{\pi x}}\left\{P_0(x)\sin\left(x-\frac{\pi}{4}\right)+Q_0(x)\cos\left(x-\frac{\pi}{4}\right)\right\}$$

$$\text{where } P_0(x) = \sum_{r=0}^{8} c_r T_r(t),$$

$$\text{and } Q_0(x) = \frac{8}{x}\sum_{r=0}^{8} d_r T_r(t), \text{ with } t = 2\left(\frac{8}{x}\right)^2 - 1.$$

For x near zero, $Y_0(x) \tilde{=} \frac{2}{\pi}\left(\ln\left(\frac{x}{2}\right)+\gamma\right)$, where γ denotes Euler's constant. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For very large x, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the phase of oscillation of $Y_0(x)$; only the amplitude, $\sqrt{\frac{2}{\pi x}}$, can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision: the routine will fail if $x \tilde{>} 1/\text{machine precision}$ (see the Users' Note for your implementation for details).

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

[2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0.0.

```
 2:  IFAIL -- INTEGER                                    Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     X is too large. On soft failure the routine returns the
     amplitude of the Y  oscillation, \/2/(pi)x.
                      0

IFAIL= 2
     X <= 0.0, Y  is undefined. On soft failure the routine
                0
     returns zero.

7. Accuracy

Let (delta) be the relative error in the argument and E be the
absolute error in the result. (Since Y (x) oscillates about zero,
                                       0
absolute error and not relative error is significant, except for
very small x.)

If (delta) is somewhat larger than the machine representation
error (e.g. if (delta) is due to data errors etc), then E and
(delta) are approximately related by

                       E~=|xY (x)|(delta)
                             1

(provided E is also within machine bounds). Figure 1 displays the
behaviour of the amplification factor |xY (x)|.
                                        1

                           Figure 1
            Please see figure in printed Reference Manual

However, if (delta) is of the same order as the machine
representation errors, then rounding errors could make E slightly
larger than the above relation predicts.
```

For very small x, the errors are essentially independent of
(delta) and the routine should provide relative accuracy bounded
by the machine precision.

For very large x, the above relation ceases to apply. In this

region, $Y_0(x) \tilde{=} \sqrt{\frac{2}{(pi)x}}\sin\left(x - \frac{(pi)}{4}\right)$. The amplitude
can be calculated with reasonable accuracy for all x, but
$\sin\left(x - \frac{(pi)}{4}\right)$ cannot. If $x - \frac{(pi)}{4}$ is written as $2N(pi)+(theta)$
where N is an integer and $0 \le (theta) < 2(pi)$, then $\sin\left(x - \frac{(pi)}{4}\right)$ is
determined by (theta) only. If $x > \tilde{} (delta)^{-1}$, (theta) cannot be
determined with any accuracy at all. Thus if x is greater than,
or of the order of the inverse of machine precision, it is
impossible to calculate the phase of $Y_0(x)$ and the routine must
fail.

8. Further Comments

For details of the time taken by the routine see the Users' Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S17 -- Approximations of Special Functions S17ADF
S17ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

```
S17ADF returns the value of the Bessel Function Y (x), via the
                                                  1
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S17ADF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Bessel Function of
the second kind Y (x).
                1

Note: Y (x) is undefined for x<=0 and the routine will fail for
       1
such arguments.

The routine is based on four Chebyshev expansions:

For 0<x<=8,

             2      x --'           2     x --'
      Y (x)= ----lnx - >   a T (t)- ----x+ - >   b T (t) , with t
       1     (pi)    8 --   r r     (pi)   8 --   r r
                       r=0                   r=0
                 2
               ( x)
             =2( -) -1;
               ( 8)

For x>8,

                  /   2  {        (    (pi))         (    (pi))}
           Y (x)=  /  -----{P (x)sin(x-3 ----)+Q (x)cos(x-3 ----)}
            1    \/   (pi)x{ 1      (     4  )  1      (     4  )}

                     --'
                     >
           where P (x)=   c T (t),
                  1     --   r r
                        r=0
                                              2
                     8 --'                  ( 8)
           and Q (x)= - >   d T (t), with t=2( -) -1.
                1     x --   r r             ( x)
```

r=0

2
For x near zero, Y (x)~=- -----. This approximation is used when
1 (pi)x
x is sufficiently small for the result to be correct to machine precision. For extremely small x, there is a danger of overflow
2
in calculating - ----- and for such arguments the routine will
(pi)x
fail.

For very large x, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

/ 2
phase of oscillation of Y (x), only the amplitude, / -----,
1 \/ (pi)x
can be determined and this is returned on soft failure. The range for which this occurs is roughly related to machine precision; the routine will fail if x>~1/machine precision (see the Users' Note for your implementation for details).

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

[2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0.0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large. On soft failure the routine returns the

amplitude of the Y_1 oscillation, $\sqrt{\frac{2}{\pi x}}$.

IFAIL= 2
$X \leq 0.0$, Y_1 is undefined. On soft failure the routine returns zero.

IFAIL= 3
X is too close to zero, there is a danger of overflow. On soft failure, the routine returns the value of $Y_1(x)$ at the smallest valid argument.

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since $Y_1(x)$ oscillates about zero, absolute error and not relative error is significant, except for very small x.)

If (delta) is somewhat larger than the machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by:

$$E \tilde{=} |xY_0(x) - Y_1(x)| (\delta)$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor $|xY_0(x) - Y_1(x)|$.

Figure 1
Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very small x, absolute error becomes large, but the relative error in the result is of the same order as (delta).

For very large x, the above relation ceases to apply. In this
region, $Y_1(x) \tilde{=} \frac{2}{x}\sin\left(x - \frac{3\pi}{4}\right)$. The amplitude $\frac{2}{x}$ can be
calculated with reasonable accuracy for all x, but $\sin\left(x - \frac{3\pi}{4}\right)$
cannot. If $x - \frac{3\pi}{4}$ is written as $2N\pi+\theta$ where N is an
integer and $0 \le \theta < 2\pi$, then $\sin\left(x - \frac{3\pi}{4}\right)$ is determined by
θ only. If $x > \delta^{-1}$, θ cannot be determined with
any accuracy at all. Thus if x is greater than, or of the order
of, the inverse of the machine precision, it is impossible to
calculate the phase of $Y_1(x)$ and the routine must fail.

8. Further Comments

For details of the time taken by the routine see the Users' Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AEF
S17AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17AEF returns the value of the Bessel Function $J_0(x)$, via the
routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S17AEF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the first kind $J_0(x)$.

Note: $J_0(-x)=J_0(x)$, so the approximation need only consider $x\geq 0$.

The routine is based on three Chebyshev expansions:

For $0<x\leq 8$,

$$J_0(x) = \sum_{r=0}^{\prime} a_r T_r(t), \quad \text{with } t = 2\left(\frac{x}{8}\right)^2 - 1.$$

For $x>8$,

$$J_0(x) = \sqrt{\frac{2}{\pi x}}\left\{P_0(x)\cos\left(x - \frac{\pi}{4}\right) - Q_0(x)\sin\left(x - \frac{\pi}{4}\right)\right\}$$

$$\text{where } P_0(x) = \sum_{r=0}^{\prime} b_r T_r(t),$$

$$\text{and } Q_0(x) = \frac{8}{x}\sum_{r=0}^{\prime} c_r T_r(t), \quad \text{with } t = 2\left(\frac{8}{x}\right)^2 - 1.$$

For x near zero, $J_0(x)\tilde{}=1$. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For very large x, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of $J_0(x)$; only the amplitude, $\sqrt{\frac{2}{(\pi)|x|}}$, can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if |x|>~1/machine precision (see the Users' Note for your implementation).

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large. On soft failure the routine returns the

amplitude of the J_0 oscillation, $\sqrt{\frac{2}{(\pi)|x|}}$.

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since $J_0(x)$ oscillates about zero, absolute error and not relative error is significant.)

If (delta) is somewhat larger than the machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are

approximately related by:

$$E \tilde{=} |xJ_1(x)|(\text{delta})$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor $|xJ_1(x)|$.

Figure 1
Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very large x, the above relation ceases to apply. In this region, $J_0(x) \tilde{=} \sqrt{\frac{2}{\pi|x|}}\cos\left(x - \frac{\pi}{4}\right)$. The amplitude $\sqrt{\frac{2}{\pi|x|}}$ can be calculated with reasonable accuracy for all x but $\cos\left(x - \frac{\pi}{4}\right)$ cannot. If $x - \frac{\pi}{4}$ is written as $2N\pi+\theta$ where N is an integer and $0 \le \theta < 2\pi$, then $\cos\left(x - \frac{\pi}{4}\right)$ is determined by θ only. If $x > \tilde{} (\text{delta})^{-1}$, θ cannot be determined with any accuracy at all. Thus if x is greater than, or of the order of, the inverse of the machine precision, it is impossible to calculate the phase of $J_0(x)$ and the routine must fail.

S17 -- Approximations of Special Functions                 S17AFF
        S17AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17AFF returns the value of the Bessel Function J (x), via the
                                                 1
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S17AFF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Bessel Function of
the first kind J (x).
               1

Note: J (-x)=-J (x), so the approximation need only consider x>=0
       1       1

The routine is based on three Chebyshev expansions:

For 0<x<=8,                                 2
            x --'                    ( x)
      J (x)= - >   a T (t) , with t=2( -) -1.
       1     8 --   r r              ( 8)
               r=0

For x>8,

               /  2   {        (   3(pi))         (   3(pi))}
      J (x)=  /  ----x{P (x)cos(x- -----)-Q (x)sin(x- -----)}
       1    \/   (pi) { 1      (     4  )  1      (     4  )}
```

$$\text{where} P_1(x) = \sum_{r=0}^{} b_r T_r(t),$$

$$\text{and } Q_1(x) = \frac{8}{x}\sum_{r=0}^{} c_r T_r(t), \text{ with } t = 2\left(\frac{8}{x}\right)^2 - 1.$$

For x near zero, $J_1(x) \tilde{=} \frac{x}{2}$. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For very large x, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the phase of oscillation of $J_1(x)$; only the amplitude, $\sqrt{\frac{2}{\pi|x|}}$, can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if $|x| \tilde{>} 1/\text{machine precision}$ (see the Users' Note for your implementation for details).

4. References

[2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large. On soft failure the routine returns the

$$\text{amplitude of the } J_1 \text{ oscillation, } \sqrt{\frac{2}{\pi|x|}}.$$

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since $J_1(x)$ oscillates about zero, absolute error and not relative error is significant.)

If (delta) is somewhat larger than machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by:

$$E \tilde{=} |xJ_0(x)|(\text{delta})$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor $|xJ_0(x)|$.

Figure 1
Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very large x, the above relation ceases to apply. In this region, $J_1(x) \tilde{=} \sqrt{\frac{2}{\pi|x|}}\cos\left(x - \frac{3\pi}{4}\right)$. The amplitude $\sqrt{\frac{2}{\pi|x|}}$ can be calculated with reasonable accuracy for all x

```
       (   3(pi))              3(pi)
but cos(x- -----) cannot. If x- ----- is written as
       (     4  )               4
2N(pi)+(theta) where N is an integer and 0<=(theta)<2(pi), then
   (   3(pi))                                          -1
cos(x- -----) is determined by (theta) only. If x>~(delta)  ,
   (     4  )
(theta) cannot be determined with any accuracy at all. Thus if x
is greater than, or of the order of, machine precision, it is
impossible to calculate the phase of J (x) and the routine must
                                       1
fail.

8. Further Comments

For details of the time taken by the routine see the Users' Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S17 -- Approximations of Special Functions                 S17AGF
        S17AGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17AGF returns a value for the Airy function, Ai(x), via the
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S17AGF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description
```

```
This routine evaluates an approximation to the Airy function,
Ai(x). It is based on a number of Chebyshev expansions:

For x<-5,

                          a(t)sinz-b(t)cosz
                  Ai(x)= -----------------
                                 1/4
                             (-x)

         (pi)  2  /  3
where z= ----+ -\/ -x , and a(t) and b(t) are expansions in the
          4    3
                 3
             ( 5)
variable t=-2( -) -1.
             ( x)

For -5<=x<=0,

                      Ai(x)=f(t)-xg(t),
                                     3
                                  ( x)
where f and g are expansions in t=-2( -) -1.
                                  ( 5)

For 0<x<4.5,

                             -3x/2
                      Ai(x)=e     y(t),

where y is an expansion in t=4x/9-1.

For 4.5<=x<9,

                             -5x/2
                      Ai(x)=e     u(t),

where u is an expansion in t=4x/9-3.

For x>=9,

                               -z
                              e  v(t)
                       Ai(x)= -------,
                                1/4
                               x
```

```
        2  / 3                              ( 18)
where z= -\/ x  and v is an expansion in t=2( --)-1.
        3                                   ( z )
```

For |x|< the machine precision, the result is set directly to Ai(0). This both saves time and guards against underflow in intermediate calculations.

For large negative arguments, it becomes impossible to calculate the phase of the oscillatory function with any precision and so

$$\text{the routine must fail. This occurs if } x < -\left(\frac{3}{2(\text{epsilon})}\right)^{2/3}, \text{ where}$$

(epsilon) is the machine precision.

For large positive arguments, where Ai decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2
X is too large and negative. On soft failure, the routine returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential-like and here relative error is appropriate. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

$$E\tilde{}=|xAi'(x)|(\text{delta}),\quad (\text{epsilon})\tilde{}=\left|\frac{xAi'(x)}{Ai(x)}\right|(\text{delta}).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, errors are strongly damped by the function and hence will be bounded by the machine precision.

For moderate negative x, the error behaviour is oscillatory but the amplitude of the error grows like

$$\text{amplitude}\left(\frac{E}{(\text{delta})}\right)\tilde{}\ \frac{|x|^{5/4}}{\sqrt{\pi}}.$$

However the phase error will be growing roughly like $\frac{2}{3}\sqrt{|x|^3}$ and hence all accuracy will be lost for large negative arguments due to the impossibility of calculating sin and cos to any

$$\text{accuracy if}\quad \frac{2}{3}\sqrt{|x|^3} > \frac{1}{(\text{delta})}.$$

For large positive arguments, the relative error amplification is considerable:

$$(\text{epsilon})\ \ /\ 3$$

```
                                  ---------~\/ x .
                                   (delta)
```

This means a loss of roughly two decimal places accuracy for arguments in the region of 20. However very large arguments are not possible due to the danger of setting underflow and so the errors are limited in practice.

8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AHF
S17AHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AHF returns a value of the Airy function, Bi(x), via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S17AHF (X, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Airy function Bi(x). It is based on a number of Chebyshev expansions.

For x<-5,

```
                              a(t)cosz+b(t)sinz
```

$$Bi(x)= \frac{}{(-x)^{1/4}},$$

$$\text{where } z= \frac{(pi)}{4}+\frac{2}{3}\sqrt{-x}^{3} \text{ and a(t) and b(t) are expansions in the variable } t=-2\left(\frac{-5}{x}\right)-1.$$

For -5<=x<=0,

$$Bi(x)=\sqrt{3}(f(t)+xg(t)),$$

where f and g are expansions in $t=-2\left(\frac{-5}{x}\right)^{3}-1$.

For 0<x<4.5,

$$Bi(x)=e^{11x/8}y(t),$$

where y is an expansion in t=4x/9-1.

For 4.5<=x<=9,

$$Bi(x)=e^{5x/2}v(t),$$

where v is an expansion in t=4x/9-3.

For x>=9,

$$Bi(x)= \frac{e^{z}u(t)}{x^{1/4}},$$

$$\text{where } z= -\frac{2}{3}\sqrt{x}^{3} \text{ and u is an expansion in } t=2\left(\frac{--}{18}\right)-1.$$

```
        3                                  ( z )

For |x|< the machine precision, the result is set directly to
Bi(0). This both saves time and avoids possible intermediate
underflows.

For large negative arguments, it becomes impossible to calculate
the phase of the oscillating function with any accuracy so the
                                                    2/3
                                      (     3     )
routine must fail. This occurs if x<-( ----------)   , where
                                      ( 2(epsilon))
(epsilon) is the machine precision.

For large positive arguments, there is a danger of causing
overflow since Bi grows in an essentially exponential manner, so
the routine must fail.

      Functions. Dover Publications.

5. Parameters

 1:  X -- DOUBLE PRECISION                                  Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                                Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     X is too large and positive. On soft failure, the routine
     returns zero.

IFAIL= 2
     X is too large and negative. On soft failure, the routine
     returns zero.

7. Accuracy
```

For negative arguments the function is oscillatory and hence
absolute error is the appropriate measure. In the positive region
the function is essentially exponential-like and here relative
error is appropriate. The absolute error, E, and the relative
error, (epsilon), are related in principle to the relative error
in the argument, (delta), by

$$E\tilde{}=|xBi'(x)|(\text{delta}),\quad (\text{epsilon})\tilde{}=\left|\frac{xBi'(x)}{Bi(x)}\right|(\text{delta}).$$

In practice, approximate equality is the best that can be
expected. When (delta), (epsilon) or E is of the order of the
machine precision, the errors in the result will be somewhat
larger.

For small x, errors are strongly damped and hence will be bounded
essentially by the machine precision.

For moderate to large negative x, the error behaviour is clearly
oscillatory but the amplitude of the error grows like amplitude

$$\left(\frac{E}{(\text{delta})}\right)\tilde{}\ \frac{|x|^{5/4}}{\sqrt{\pi}}.$$

However the phase error will be growing roughly as $\frac{2}{3}\sqrt{|x|^3}$ and
hence all accuracy will be lost for large negative arguments.

This is due to the impossibility of calculating sin and cos to

$$\text{any accuracy if } \frac{2}{3}\sqrt{|x|^3} > \frac{1}{(\text{delta})}.$$

For large positive arguments, the relative error amplification is
considerable:

$$\frac{(\text{epsilon})}{(\text{delta})}\tilde{}\sqrt{x^3}.$$

```
This means a loss of roughly two decimal places accuracy for
arguments in the region of 20. However very large arguments are
not possible due to the danger of causing overflow and errors are
therefore limited in practice.

8. Further Comments

your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17AJF returns a value of the derivative of the Airy function
Ai(x), via the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S17AJF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the derivative of the
Airy function Ai(x). It is based on a number of Chebyshev
expansions.

For x<-5,

                       4   [           b(t)     ]
              Ai'(x)=\/-x[a(t)cosz+ ------sinz],
```

```
                              [          (zeta)    ]

         (pi)                 2  /  3
where z= -----+(zeta), (zeta)= -\/ -x  and a(t) and b(t) are
          4                   3
                               3
                            ( 5)
expansions in variable t=-2( -) -1.
                            ( x)

For -5<=x<=0,

                                2
                        Ai'(x)=x f(t)-g(t),
                                          3
                                       ( x)
where f and g are expansions in t=-2( -) -1.
                                       ( 5)

For 0<x<4.5,

                                -11x/8
                        Ai'(x)=e      y(t),

                                  ( x)
where y(t) is an expansion in t=4( -)-1.
                                  ( 9)

For 4.5<=x<9,

                                -5x/2
                        Ai'(x)=e     v(t),

                                  ( x)
where v(t) is an expansion in t=4( -)-3.
                                  ( 9)

For x>=9,

                               4    -z
                        Ai'(x)=\/-xe  u(t),

         2  / 3                                  ( 18)
where z= -\/ x  and u(t) is an expansion in t=2( --)-1.
         3                                       ( z )

For |x|< the square of the machine precision, the result is set
```

directly to Ai'(0). This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy and so

$$\text{the routine must fail. This occurs for } x < -\left(\frac{\pi}{\varepsilon}\right)^{4/7},$$

where (epsilon) is the machine precision.

For large positive arguments, where Ai' decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2
X is too large and negative. On soft failure, the routine returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region

the function is essentially exponential in character and here relative error is needed. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

$$E \tilde{=} |x\ \mathrm{Ai}(x)|^2 (\mathrm{delta}) \qquad (\mathrm{epsilon}) \tilde{=} \left| \frac{x\ \mathrm{Ai}(x)^2}{\mathrm{Ai}'(x)} \right| (\mathrm{delta}).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, positive or negative, errors are strongly attenuated by the function and hence will be roughly bounded by the machine precision.

For moderate to large negative x, the error, like the function, is oscillatory; however the amplitude of the error grows like

$$\frac{|x|^{7/4}}{\sqrt{\pi}}.$$

Therefore it becomes impossible to calculate the function with

$$\text{any accuracy if } |x|^{7/4} > \frac{\sqrt{\pi}}{(\mathrm{delta})}.$$

For large positive x, the relative error amplification is considerable:

$$\frac{(\mathrm{epsilon})}{(\mathrm{delta})} \tilde{=} \sqrt{x^3}.$$

However, very large arguments are not possible due to the danger of underflow. Thus in practice error amplification is limited.

8. Further Comments

```

```
                                ( 5)
expansions in the variable t=-2( -) -1.
                                ( x)

For -5<=x<=0,

                                 2
                    Bi'(x)=\/3(x f(t)+g(t)),
                                       3
                                   ( x)
where f and g are expansions in t=-2( -) -1.
                                   ( 5)

For 0<x<4.5,

                                3x/2
                        Bi'(x)=e    y(t),

where y(t) is an expansion in t=4x/9-1.

For 4.5<=x<9,

                               21x/8
                      Bi'(x)=e     u(t),

where u(t) is an expansion in t=4x/9-3.

For x>=9,

                               4   z
                        Bi'(x)=\/xe v(t),

        2  / 3                                  ( 18)
where z= -\/ x  and v(t) is an expansion in t=2( --)-1.
        3                                       ( z )

For |x|< the square of the machine precision, the result is set
directly to Bi'(0). This saves time and avoids possible
underflows in calculation.

For large negative arguments, it becomes impossible to calculate
a result for the oscillating function with any accuracy so the
                                                    4/7
                                      (          )
                                      (  \/(pi)  )
routine must fail. This occurs for x<-( ---------)   , where
                                      ( (epsilon))
(epsilon) is the machine precision.
```

For large positive arguments, where Bi' grows in an essentially exponential manner, there is a danger of overflow so the routine must fail.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large and positive. On soft failure the routine returns zero.

IFAIL= 2
X is too large and negative. On soft failure the routine returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is appropriate. In the positive region the function has essentially exponential behaviour and hence relative error is needed. The absolute error, E, and the relative error (epsilon), are related in principle to the relative error in the argument (delta), by

$$E \approx |x\,\mathrm{Bi}(x)|\,(\mathrm{delta}) \qquad (\mathrm{epsilon}) \approx \left|\frac{x\,\mathrm{Bi}(x)}{\mathrm{Bi}'(x)}\right|(\mathrm{delta}).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the

machine precision, the errors in the result will be somewhat larger.

For small x, positive or negative, errors are strongly attenuated by the function and hence will effectively be bounded by the machine precision.

For moderate to large negative x, the error is, like the function, oscillatory. However, the amplitude of the absolute

$$\text{error grows like } \frac{|x|^{7/4}}{\sqrt{\pi}}.$$

Therefore it becomes impossible to calculate the function with any accuracy if

$$|x|^{7/4} > \frac{\sqrt{\pi}}{\text{(delta)}}.$$

For large positive x, the relative error amplification is

$$\text{considerable: } \frac{\text{(epsilon)}}{\text{(delta)}} \tilde{\sqrt{x}}\,.$$

However, very large arguments are not possible due to the danger of overflow. Thus in practice the actual amplification that occurs is limited.

8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

S17 -- Approximations of Special Functions S17DCF
S17DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details.

```
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17DCF returns a sequence of values for the Bessel functions
Y      (z) for complex z, non-negative (nu) and n=0,1,...,N-1,
 (nu)+n
with an option for exponential scaling.

2. Specification

       SUBROUTINE S17DCF (FNU, Z, N, SCALE, CY, NZ, CWRK, IFAIL)
       INTEGER              N, NZ, IFAIL
       DOUBLE PRECISION     FNU
       COMPLEX(KIND(1.0D0)) Z, CY(N), CWRK(N)
       CHARACTER*1          SCALE

3. Description

This subroutine evaluates a sequence of values for the Bessel
function Y    (z), where z is complex, -(pi) < arg z <= (pi), and
          (nu)
(nu) is the real, non-negative order. The N-member sequence is
generated for orders (nu), (nu)+1,...,(nu)+N-1. Optionally, the
                                    -|Im z|
sequence is scaled by the factor e       .

Note: although the routine may not be called with (nu) less than
zero, for negative orders the formula
Y     (z)=Y    (z)cos((pi)(nu))+J    (z)sin((pi)(nu)) may be used
 -(nu)     (nu)                 (nu)
(for the Bessel function J    (z), see S17DEF).
                          (nu)

The routine is derived from the routine CBESY in Amos [2]. It is
                                  (1)      (2)
                                 H    (z)-H    (z)
                                  (nu)     (nu)            (1)
based on the relation Y    (z)= -----------------, where H    (z)
                       (nu)            2i                 (nu)
     (2)
and H    (z) are the Hankel functions of the first and second
     (nu)
kinds respectively (see S17DLF).

When N is greater than 1, extra values of Y    (z) are computed
                                           (nu)
using recurrence relations.
```

```
For very large |z| or ((nu)+N-1), argument reduction will cause
total loss of accuracy, and so no computation is performed. For
slightly smaller |z| or ((nu)+N-1), the computation is performed
but results are accurate to less than half of machine precision.
If |z| is very small, near the machine underflow threshold, or
((nu)+N-1) is too large, there is a risk of overflow and so no
computation is performed. In all the above cases, a warning is
given by the routine.

      Functions. Dover Publications.

[2]   Amos D E (1986) Algorithm 644: A Portable Package for Bessel
      Functions of a Complex Argument and Nonnegative Order. ACM
      Trans. Math. Softw. 12 265--273.

5. Parameters

 1:  FNU -- DOUBLE PRECISION                                  Input
     On entry: the order, (nu), of the first member of the
     sequence of functions. Constraint: FNU >= 0.0.

 2:  Z -- COMPLEX(KIND(1.0D0))                                Input
     On entry: the argument, z, of the functions. Constraint: Z
     /= (0.0, 0.0).

 3:  N -- INTEGER                                             Input
     On entry: the number, N, of members required in the sequence
     Y    (z), Y      (z),...,Y        (z). Constraint: N >= 1.
      (nu)      (nu)+1         (nu)+N-1

 4:  SCALE -- CHARACTER*1                                     Input
     On entry: the scaling option.

     If SCALE = 'U', the results are returned unscaled.

     If SCALE = 'S', the results are returned scaled by the
             -|Imz|
     factor e      . Constraint: SCALE = 'U' or 'S'.

 5:  CY(N) -- COMPLEX(KIND(1.0D)) array                       Output
     On exit: the N required function values: CY(i) contains
     Y        (z), for i=1,2,...,N.
      (nu)+i-1

 6:  NZ -- INTEGER                                            Output
     On exit: the number of components of CY that are set to zero
     due to underflow. The positions of such components in the
```

```
     array CY are arbitrary.

 7:  CWRK(N) -- COMPLEX(KIND(1.0D)) array                Workspace

 8:  IFAIL -- INTEGER                                    Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry FNU < 0.0,

     or       Z = (0.0, 0.0),

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because ABS(Z) is less than a machine-dependent
     threshold value (given in the Users' Note for your
     implementation).

IFAIL= 3
     No computation has been performed due to the likelihood of
     overflow, because FNU + N - 1 is too large - how large
     depends on Z as well as the overflow threshold of the
     machine.

IFAIL= 4
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S17DCF are accurate to less
     than half of machine precision. This error exit may occur if
     either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 5
```

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DCF would be lost. This error exit may occur if either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DCF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S17DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S17DCF, the actual number of correct digits is limited, in general, by p-s, where s~max(1,|log |z||,|log (nu)|) represents the number of digits
          10   10
lost due to the argument reduction. Thus the larger the values of |z| and (nu), the less the precision in the result. If S17DCF is called with N>1, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DCF with different base values of (nu) and different N, the computed values may not agree exactly. Empirical tests with modest values of (nu) and z have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S17DCF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S17DCF with N greater than 1, rather than to make N separate calls to S17DCF.

Paradoxically, for some values of z and (nu), it is cheaper to call S17DCF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

```
Note that if the function required is Y (x) or Y (x), i.e., (nu)
                                       0        1
= 0.0 or 1.0, where x is real and positive, and only a single
unscaled function value is required, then it may be much cheaper
to call S17ACF or S17ADF respectively.

9. Example

The example program prints a caption and then proceeds to read
sets of data from the input data stream. The first datum is a
value for the order FNU, the second is a complex value for the
argument, Z, and the third is a value for the parameter SCALE.
The program calls the routine with N = 2 to evaluate the function
for orders FNU and FNU + 1, and it prints the results. The
process is repeated until the end of the input data stream is
encountered.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S17 -- Approximations of Special Functions                S17DEF
        S17DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17DEF returns a sequence of values for the Bessel functions
J      (z) for complex z, non-negative (nu) and n=0,1,...,N-1,
 (nu)+n
with an option for exponential scaling.

2. Specification

       SUBROUTINE S17DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
       INTEGER              N, NZ, IFAIL
       DOUBLE PRECISION     FNU
       COMPLEX(KIND(1.0D0)) Z, CY(N)
       CHARACTER*1          SCALE

3. Description

This subroutine evaluates a sequence of values for the Bessel
```

function J (z), where z is complex, -(pi) < arg z <= (pi), and
(nu)
(nu) is the real, non-negative order. The N-member sequence is
generated for orders (nu), (nu)+1,...,(nu)+N-1. Optionally, the
-|Im z|
sequence is scaled by the factor e .

Note: although the routine may not be called with (nu) less than
zero, for negative orders the formula
J (z)=J (z)cos((pi)(nu))-Y (z)sin((pi)(nu)) may be used
-(nu) (nu) (nu)
(for the Bessel function Y (z), see S17DCF).
(nu)

The routine is derived from the routine CBESJ in Amos [2]. It is
(nu)(pi)i/2
based on the relations J (z)=e I (-iz), Im z>=0.0
(nu) (nu)
-(nu)(pi)i/2
and J (z)=e I (iz), Im z<0.0.
(nu) (nu)

The Bessel function I (z) is computed using a variety of
(nu)
techniques depending on the region under consideration.

When N is greater than 1, extra values of J (z) are computed
(nu)
using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause
total loss of accuracy, and so no computation is performed. For
slightly smaller |z| or ((nu)+N-1), the computation is performed
but results are accurate to less than half of machine precision.
If Im z is large, there is a risk of overflow and so no
computation is performed. In all the above cases, a warning is
given by the routine.

Functions. Dover Publications.

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel
Functions of a Complex Argument and Nonnegative Order. ACM
Trans. Math. Softw. 12 265--273.

5. Parameters

1: FNU -- DOUBLE PRECISION Input

```
     On entry: the order, (nu), of the first member of the
     sequence of functions. Constraint: FNU >= 0.0.

 2:  Z -- COMPLEX(KIND(1.0D0))                                  Input
     On entry: the argument z of the functions.

 3:  N -- INTEGER                                               Input
     On entry: the number, N, of members required in the sequence
     J    (z),J      (z),...,J        (z). Constraint: N >= 1.
      (nu)     (nu)+1          (nu)+N-1

 4:  SCALE -- CHARACTER*1                                       Input
     On entry: the scaling option.
          If SCALE = 'U', the results are returned unscaled.

          If SCALE = 'S', the results are returned scaled by the
                  -|Imz|
          factor e      .
     Constraint: SCALE = 'U' or 'S'.

 5:  CY(N) -- COMPLEX(KIND(1.0D)) array                         Output
     On exit: the N required function values: CY(i) contains
     J        (z), for i=1,2,...,N.
      (nu)+i-1

 6:  NZ -- INTEGER                                              Output
     On exit: the number of components of CY that are set to zero
     due to underflow. If NZ > 0, then elements CY(N-NZ+1), CY(N-
     NZ+2),...,CY(N) are set to zero.

 7:  IFAIL -- INTEGER                                   Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry FNU < 0.0,

     or       N < 1,
```

```
     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because Im Z is larger than a machine-dependent
     threshold value (given in the Users' Note for your
     implementation). This error exit can only occur when SCALE =
     'U'.

IFAIL= 3
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S17DEF are accurate to less
     than half of machine precision. This error exit may occur if
     either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 4
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S17DEF would be lost. This
     error exit may occur when either ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 5
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DEF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S17DEF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DEF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |(|z|),|log  (nu)|) represents the number of digits
           10           10
lost due to the argument reduction. Thus the larger the values of
|z| and (nu), the less the precision in the result. If S17DEF is
called with N>1, then computation of function values via
recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are
computed by calls to S17DEF with different base values of (nu)
```

```
and different N, the computed values may not agree exactly.
Empirical tests with modest values of (nu) and z have shown that
the discrepancy is limited to the least significant 3-4 digits of
precision.

8. Further Comments

The time taken by the routine for a call of S17DEF is
approximately proportional to the value of N, plus a constant. In
general it is much cheaper to call S17DEF with N greater than 1,
rather than to make N separate calls to S17DEF.

Paradoxically, for some values of z and (nu), it is cheaper to
call S17DEF with a larger value of N than is required, and then
discard the extra function values returned. However, it is not
possible to state the precise circumstances in which this is
likely to occur. It is due to the fact that the base value used
to start recurrence may be calculated in different regions for
different N, and the costs in each region may differ greatly.

Note that if the function required is J (x) or J (x), i.e., (nu)
                                      0        1
= 0.0 or 1.0, where x is real and positive, and only a single
unscaled function value is required, then it may be much cheaper
to call S17AEF or S17AFF respectively.

9. Example

The example program prints a caption and then proceeds to read
sets of data from the input data stream. The first datum is a
value for the order FNU, the second is a complex value for the
argument, Z, and the third is a value for the parameter SCALE.

The program calls the routine with N = 2 to evaluate the function
for orders FNU and FNU + 1, and it prints the results. The
process is repeated until the end of the input data stream is
encountered.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S17 -- Approximations of Special Functions                S17DGF
       S17DGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
```

not included in the Foundation Library.

1. Purpose

S17DGF returns the value of the Airy function Ai(z) or its derivative Ai'(z) for complex z, with an option for exponential scaling.

2. Specification

```
SUBROUTINE S17DGF (DERIV, Z, SCALE, AI, NZ, IFAIL)
INTEGER              NZ, IFAIL
COMPLEX(KIND(1.0D0)) Z, AI
CHARACTER*1          DERIV, SCALE
```

3. Description

This subroutine returns a value for the Airy function Ai(z) or its derivative Ai'(z), where z is complex, -(pi) < arg z <= (pi).

Optionally, the value is scaled by the factor $e^{2z\sqrt{z}/3}$.

The routine is derived from the routine CAIRY in Amos [2]. It is based on the relations

$$Ai(z)= \frac{\sqrt{zK_{1/3}(w)}}{(pi)\sqrt{3}}, \text{ and } Ai'(z)= \frac{-zK_{2/3}(w)}{(pi)/3},$$

where $K_{(nu)}$ is the modified Bessel function and $w=2z\sqrt{z}/3$.

For very large |z|, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z|, the computation is performed but results are accurate to less than half of machine precision. If Re w is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: DERIV -- CHARACTER*1 Input
On entry: specifies whether the function or its derivative is required.
If DERIV = 'F', Ai(z) is returned.

If DERIV = 'D', Ai'(z) is returned.
Constraint: DERIV = 'F' or 'D'.

2: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the function.

3: SCALE -- CHARACTER*1 Input
On entry: the scaling option.

If SCALE = 'U', the result is returned unscaled.

If SCALE = 'S', the result is returned scaled by the factor

$$e^{2z\sqrt{z}/3}$$

. Constraint: SCALE = 'U' or 'S'.

4: AI -- COMPLEX(KIND(1.0D0)) Output
On exit: the required function or derivative value.

5: NZ -- INTEGER Output
On exit: NZ indicates whether or not AI is set to zero due to underflow. This can only occur when SCALE = 'U'.

If NZ = 0, AI is not set to zero.

If NZ = 1, AI is set to zero.

6: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

```
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry DERIV /= 'F' or 'D'.

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of

     overflow, because Re w is too large, where w=2Z\/Z/3 -- how
     large depends on Z and the overflow threshold of the
     machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the result returned by S17DGF is accurate to less than
     half of machine precision. This error exit may occur if ABS
     (Z) is greater than a machine-dependent threshold value
     (given in the Users' Note for your implementation).

IFAIL= 4
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in the result returned by S17DGF would be lost.
     This error exit may occur if ABS(Z) is greater than a
     machine-dependent threshold value (given in the Users' Note
     for your implementation).

IFAIL= 5
     No result is returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DGF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S17DGF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DGF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |z||) represents the number of digits lost due to
```

```
            10
the argument reduction. Thus the larger the value of |z|, the
less the precision in the result.

Empirical tests with modest values of z, checking relations
between Airy functions Ai(z), Ai'(z), Bi(z) and Bi'(z), have
shown errors limited to the least significant 3-4 digits of
precision.

8. Further Comments

Note that if the function is required to operate on a real
argument only, then it may be much cheaper to call S17AGF or
S17AJF.

9. Example

The example program prints a caption and then proceeds to read
sets of data from the input data stream. The first datum is a
value for the parameter DERIV, the second is a complex value for
the argument, Z, and the third is a value for the parameter
SCALE. The program calls the routine and prints the results. The
process is repeated until the end of the input data stream is
encountered.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S17 -- Approximations of Special Functions                S17DHF
        S17DHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17DHF returns the value of the Airy function Bi(z) or its
derivative Bi'(z) for complex z, with an option for exponential
scaling.

2. Specification

       SUBROUTINE S17DHF (DERIV, Z, SCALE, BI, IFAIL)
       INTEGER              IFAIL
```

```
      COMPLEX(KIND(1.0D0)) Z, BI
      CHARACTER*1          DERIV, SCALE
```

3. Description

This subroutine returns a value for the Airy function Bi(z) or its derivative Bi'(z), where z is complex, -(pi) < argz <= (pi).

Optionally, the value is scaled by the factor $e^{|\mathrm{Re}\,(2z\sqrt{z}/3)|}$.

The routine is derived from the routine CBIRY in Amos [2]. It is based on the relations $Bi(z)= \frac{\sqrt{z}}{3}(I_{-1/3}(w)+I_{1/3}(w))$, and $Bi'(z)= \frac{z}{\sqrt{3}}(I_{-2/3}(w)+I_{2/3}(w))$, where $I_{(nu)}$ is the modified Bessel function and $w=2z\sqrt{z}/3$.

For very large |z|, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z|, the computation is performed but results are accurate to less than half of machine precision. If Re z is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

[2] Hammersley J M and Handscomb D C (1967) Monte-Carlo Methods. Methuen.

5. Parameters

1: DERIV -- CHARACTER*1 Input
On entry: specifies whether the function or its derivative is required.
If DERIV = 'F', Bi(z) is returned.

```
          If DERIV = 'D', Bi'(z) is returned.
     Constraint: DERIV = 'F' or 'D'.

 2:  Z -- COMPLEX(KIND(1.0D0))                                  Input
     On entry: the argument z of the function.

 3:  SCALE -- CHARACTER*1                                       Input
     On entry: the scaling option.
          If SCALE = 'U', the result is returned unscaled.

          If SCALE = 'S', the result is returned scaled by the

                  |Re(2z\/z/3)|
          factor e             .
     Constraint: SCALE = 'U' or 'S'.

 4:  BI -- COMPLEX(KIND(1.0D0))                                 Output
     On exit: the required function or derivative value.

 5:  IFAIL -- INTEGER                                       Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry DERIV /= 'F' or 'D'.

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because real(Z) is too large - how large depends
     on the overflow threshold of the machine. This error exit
     can only occur when SCALE = 'U'.

IFAIL= 3
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the result returned by S17DHF is accurate to less than
```

half of machine precision. This error exit may occur if ABS (Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DHF would be lost. This error exit may occur if ABS(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5
No result is returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DHF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S17DHF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S17DHF, the actual number of correct digits is limited, in general, by p-s, where s~max(1,|log |z||) represents the number of digits lost due to
            10
the argument reduction. Thus the larger the value of |z|, the less the precision in the result.

Empirical tests with modest values of z, checking relations between Airy functions Ai(z), Ai'(z), Bi(z) and Bi'(z), have shown errors limited to the least significant 3-4 digits of precision.

8. Further Comments

Note that if the function is required to operate on a real argument only, then it may be much cheaper to call S17AHF or S17AKF.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The

```
process is repeated until the end of the input data stream is
encountered.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

```
S17 -- Approximations of Special Functions                S17DLF
        S17DLF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S17DLF returns a sequence of values for the Hankel functions
 (1)          (2)
H      (z) or H      (z) for complex z, non-negative (nu) and
 (nu)+n       (nu)+n
n=0,1,...,N-1, with an option for exponential scaling.

2. Specification

       SUBROUTINE S17DLF (M, FNU, Z, N, SCALE, CY, NZ, IFAIL)
       INTEGER              M, N, NZ, IFAIL
       DOUBLE PRECISION     FNU
       COMPLEX(KIND(1.0D0)) Z, CY(N)
       CHARACTER*1          SCALE

3. Description

This subroutine evaluates a sequence of values for the Hankel
          (1)         (2)
function H    (z) or H    (z), where z is complex, -(pi) < argz
          (nu)        (nu)
<= (pi), and (nu) is the real, non-negative order. The N-member
sequence is generated for orders (nu), (nu)+1,...,(nu)+N-1.
                                                      -iz
Optionally, the sequence is scaled by the factor e    if the
             (1)                       iz
function is H    (z) or by the factor e   if the function is
             (nu)
 (2)
H    (z).
 (nu)
```

Note: although the routine may not be called with (nu) less than zero, for negative orders the formulae
 (1)   (nu)(pi)i (1)   (2)   -(nu)(pi)i (2)
H   (z)=e   H   (z), and H   (z)=e   H   (z)
 -(nu)   (nu)   -(nu)   (nu)
may be used.

The routine is derived from the routine CBESH in Amos [2]. It is based on the relation

$$H^{(m)}_{(nu)}(z) = -e^{1 -p(nu)}\, K^{-p}_{(nu)}(ze^{\ }),$$

where $p = i\,\frac{(pi)}{2}$ if $m=1$ and $p=-i\,\frac{(pi)}{2}$ if $m=2$, and the Bessel function $K^{(nu)}_{\ }(z)$ is computed in the right half-plane only. Continuation of $K^{(nu)}_{\ }(z)$ to the left half-plane is computed in terms of the Bessel function $I^{(nu)}_{\ }(z)$. These functions are evaluated using a variety of different techniques, depending on the region under consideration.

When N is greater than 1, extra values of $H^{(m)}_{(nu)}(z)$ are computed using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z| or ((nu)+N-1), the computation is performed but results are accurate to less than half of machine precision. If |z| is very small, near the machine underflow threshold, or ((nu)+N-1) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: M -- INTEGER Input
On entry: the kind of functions required.
(1)
If M = 1, the functions are H (z).
(nu)

(2)
If M = 2, the functions are H (z).
(nu)
Constraint: M = 1 or 2.

2: FNU -- DOUBLE PRECISION Input
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.

3: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the functions. Constraint: Z /= (0.0, 0.0).

4: N -- INTEGER Input
On entry: the number, N, of members required in the sequence
(M) (M) (M)
H , H ,..., H . Constraint: N >= 1.
(nu) (nu)+1 (nu)+N-1

5: SCALE -- CHARACTER*1 Input
On entry: the scaling option.
If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the
-iz iz
factor e when M = 1, or by the factor e when M = 2.
Constraint: SCALE = 'U' or 'S'.

6: CY(N) -- COMPLEX(KIND(1.0D)) array Output
On exit: the N required function values: CY(i) contains
(M)
H , for i=1,2,...,N.
(nu)+i-1

7: NZ -- INTEGER Output
On exit: the number of components of CY that are set to zero due to underflow. If NZ > 0, then if Imz>0.0 and M = 1, or Imz<0.0 and M = 2, elements CY(1), CY(2),...,CY(NZ) are set to zero. In the complementary half-planes, NZ simply states the number of underflows, and not which elements they are.

```
 8:  IFAIL -- INTEGER                                    Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry M /= 1 and M /= 2,

     or       FNU < 0.0,

     or       Z = (0.0, 0.0),

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because ABS(Z) is less than a machine-dependent
     threshold value (given in the Users' Note for your
     implementation).

IFAIL= 3
     No computation has been performed due to the likelihood of
     overflow, because FNU + N - 1 is too large - how large
     depends on Z and the overflow threshold of the machine.

IFAIL= 4
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S17DLF are accurate to less
     than half of machine precision. This error exit may occur if
     either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 5
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S17DLF would be lost. This
```

```
     error exit may occur when either of ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 6
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S17DLF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S17DLF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DLF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |z||,|log  (nu)|) represents the number of digits
            10         10
lost due to the argument reduction. Thus the larger the values of
|z| and (nu), the less the precision in the result. If S17DLF is
called with N>1, then computation of function values via
recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are
computed by calls to S17DLF with different base values of (nu)
and different N, the computed values may not agree exactly.
Empirical tests with modest values of (nu) and z have shown that
the discrepancy is limited to the least significant 3-4 digits of
precision.

8. Further Comments

The time taken by the routine for a call of S17DLF is
approximately proportional to the value of N, plus a constant. In
general it is much cheaper to call S17DLF with N greater than 1,
rather than to make N separate calls to S17DLF.

Paradoxically, for some values of z and (nu), it is cheaper to
call S17DLF with a larger value of N than is required, and then
discard the extra function values returned. However, it is not
possible to state the precise circumstances in which this is
likely to occur. It is due to the fact that the base value used
to start recurrence may be calculated in different regions for
different N, and the costs in each region may differ greatly.

9. Example
```

```
          The example program prints a caption and then proceeds to read
          sets of data from the input data stream. The first datum is a
          value for the kind of function, M, the second is a value for the
          order FNU, the third is a complex value for the argument, Z, and
          the fourth is a value for the parameter SCALE. The program calls
          the routine with N = 2 to evaluate the function for orders FNU
          and FNU + 1, and it prints the results. The process is repeated
          until the end of the input data stream is encountered.

          The example program is not reproduced here. The source code for
          all example programs is distributed with the NAG Foundation
          Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

          S18 -- Approximations of Special Functions                 S18ACF
                  S18ACF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S18ACF returns the value of the modified Bessel Function K (x),
                                                                    0
          via the routine name.

          2. Specification

                 DOUBLE PRECISION FUNCTION S18ACF (X, IFAIL)
                 INTEGER          IFAIL
                 DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the modified Bessel
          Function of the second kind K (x).
                                       0

          Note: K (x) is undefined for x<=0 and the routine will fail for
                 0
          such arguments.

          The routine is based on five Chebyshev expansions:

          For 0<x<=1,

                           --'          --'                    2
```

```
      K (x)=-lnx >   a T (t)+ >   b T (t) , where t=2x -1;
       0         --   r r     --   r r
                 r=0          r=0
```

For 1<x<=2,

```
                    -x --'
                K (x)=e   >   c T (t) , where t=2x-3;
                 0        --   r r
                          r=0
```

For 2<x<=4,

```
                    -x --'
                K (x)=e   >   d T (t) , where t=x-3;
                 0        --   r r
                          r=0
```

For x>4,

```
                     -x
                    e   --'                      9-x
                K (x)= --- >   e T (t) , where t= ---.
                 0         --   r r              1+x
                       \/x r=0
```

For x near zero, $K_0(x) \tilde{=} -(\gamma) - \ln(x/2)$, where (γ) denotes Euler's constant. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For large x, where there is a danger of underflow due to the smallness of K_0, the result is set exactly to zero.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0.0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential

```
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     X <= 0.0, K  is undefined. On soft failure the routine
               0
     returns zero.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and result respectively.

If (delta) is somewhat larger than the machine precision (i.e.,
if (delta) is due to data errors etc), then (epsilon) and (delta)
are approximately related by:

                              | xK (x)|
                              |   1   |
                   (epsilon)~=| ------|(delta).
                              | K (x) |
                              |  0    |

Figure 1 shows the behaviour of the error amplification factor

                             | xK (x)|
                             |   1   |
                             | ------|.
                             | K (x) |
                             |  0    |

                            Figure 1
          Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision,
then rounding errors could make (epsilon) slightly larger than
the above relation predicts.

                                                          |  1 |
For small x, the amplification factor is approximately    | ---|,
                                                          | lnx|
which implies strong attenuation of the error, but in general
(epsilon) can never be less than the machine precision.
```

```
For large x, (epsilon)~=x(delta) and we have strong amplification
of the relative error. Eventually K , which is asymptotically
                                   0
          -x
         e
given by  ---, becomes so small that it cannot be calculated

         \/x
without underflow and hence the routine will return zero. Note
that for large x the errors will be dominated by those of the
Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the appropriate
the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
```

```
S18 -- Approximations of Special Functions                S18ADF
        S18ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S18ADF returns the value of the modified Bessel Function K (x),
                                                          1
via the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S18ADF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description
```

```
This routine evaluates an approximation to the modified Bessel
Function of the second kind K (x).
                             1

Note: K (x) is undefined for x<=0 and the routine will fail for
       1
such arguments.

The routine is based on five Chebyshev expansions:

For 0<x<=1,

           1      --'           --'                     2
    K (x)= -+xlnx >   a T (t)-x >   b T (t) , where t=2x -1;
     1     x      --   r r      --   r r
                  r=0           r=0

For 1<x<=2,

                      -x --'
              K (x)=e   >   c T (t) , where t=2x-3;
               1        --   r r
                        r=0

For 2<x<=4,

                      -x --'
              K (x)=e   >   d T (t) , where t=x-3;
               1        --   r r
                        r=0

For x>4,

                      -x
                     e   --'                    9-x
             K (x)= --- >   e T (t) , where t= ---.
              1         --   r r               1+x
                    \/x r=0

                         1
For x near zero, K (x)~= -. This approximation is used when x is
                 1       x
sufficiently small for the result to be correct to machine
precision. For very small x on some machines, it is impossible to
           1
calculate  - without overflow and the routine must fail.
           x

For large x, where there is a danger of underflow due to the
```

smallness of K , the result is set exactly to zero.
              1

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X > 0.0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X <= 0.0, K is undefined. On soft failure the routine
           1
returns zero.

IFAIL= 2
X is too small, there is a danger of overflow. On soft failure the routine returns approximately the largest representable value.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\text{epsilon}) \approx \left| \frac{x K_0(x) - K_1(x)}{K_1(x)} \right| (\text{delta}).$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{xK_0(x) - K_1(x)}{K_1(x)} \right|.$$

Figure 1
Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon)~=(delta) and there is no amplification of errors.

For large x, (epsilon)~=x(delta) and we have strong amplification of the relative error. Eventually K_1, which is asymptotically given by $\frac{e^{-x}}{\sqrt{x}}$, becomes so small that it cannot be calculated without underflow and hence the routine will return zero. Note that for large x the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S18 -- Approximations of Special Functions S18AEF
S18AEF -- NAG Foundation Library Routine Document

```
Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S18AEF returns the value of the modified Bessel Function I (x),
                                                          0
via the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S18AEF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the modified Bessel
Function of the first kind I (x).
                            0

Note: I (-x)=I (x), so the approximation need only consider x>=0.
       0      0

The routine is based on three Chebyshev expansions:

For 0<x<=4,

                    x --'                    ( x)
             I (x)=e  >   a T (t) , where t=2( -)-1;
              0       --   r r              ( 4)
                      r=0

For 4<x<=12,

                     x --'                    x-8
              I (x)=e  >   b T (t) , where t= ---;
               0       --   r r                4
                       r=0

For x>12,

                    x
                   e   --'                   ( 12)
           I (x)= --- >   c T (t) , where t=2( --)-1.
            0         --   r r              ( x )
                     \/x r=0
```

For small x, $I_0(x) \tilde{=} 1$. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For large x, the routine must fail because of the danger of overflow in calculating e^x.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
X is too large. On soft failure the routine returns the approximate value of $I_0(x)$ at the nearest valid argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$|\text{epsilon}| \tilde{=} \left| \frac{x I_1(x)}{I_0(x)} \right| |\text{delta}|.$$

```
                              |  0    |
```

Figure 1 shows the behaviour of the error amplification factor

```
                             | xI (x)|
                             |   1   |
                             | ------|.
                             | I (x) |
                             |  0    |
```

Figure 1
Please see figure in printed Reference Manual

However if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x the amplification factor is approximately $\frac{x^2}{2}$, which implies strong attenuation of the error, but in general (epsilon) can never be less than the machine precision.

For large x, (epsilon)~=x(delta) and we have strong amplification of errors. However the routine must fail for quite moderate values of x, because $I_0(x)$ would overflow; hence in practice the loss of accuracy for large x is not excessive. Note that for large x the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S18 -- Approximations of Special Functions S18AFF
S18AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18AFF returns a value for the modified Bessel Function $I_1(x)$, via the routine name.

2. Specification

```
      DOUBLE PRECISION FUNCTION S18AFF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind $I_1(x)$.

Note: $I_1(-x)=-I_1(x)$, so the approximation need only consider $x\geq 0$

The routine is based on three Chebyshev expansions:

For $0<x\leq 4$,

$$I_1(x)=x\sum_{r=0}^{\prime\prime} a_r T_r(t), \text{ where } t=2\left(\frac{x}{4}\right)^2-1;$$

For $4<x\leq 12$,

$$I_1(x)=e^x\sum_{r=0}^{\prime\prime} b_r T_r(t), \text{ where } t=\frac{x-8}{4};$$

For $x>12$,

$$I_1(x)=\frac{e^x}{\sqrt{x}}\sum_{r=0}^{\prime\prime} c_r T_r(t), \text{ where } t=2\left(\frac{12}{x}\right)-1.$$

For small x, I (x)~=x. This approximation is used when x is
              1
sufficiently small for the result to be correct to machine
precision.

For large x, the routine must fail because I (x) cannot be
                                            1
represented without overflow.

4. References

S18 -- Approximations of Special Functions S18DCF
S18DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is

```
not included in the Foundation Library.

1. Purpose

S18DCF returns a sequence of values for the modified Bessel
functions K      (z) for complex z, non-negative (nu) and
           (nu)+n
n=0,1,...,N-1, with an option for exponential scaling.

2. Specification

       SUBROUTINE S18DCF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
       INTEGER              N, NZ, IFAIL
       DOUBLE PRECISION     FNU
       COMPLEX(KIND(1.0D0)) Z, CY(N)
       CHARACTER*1          SCALE

3. Description

This subroutine evaluates a sequence of values for the modified
Bessel function K    (z), where z is complex, -(pi) < arg z <=
                (nu)
(pi), and (nu) is the real, non-negative order. The N-member
sequence is generated for orders (nu), (nu)+1,...,(nu)+N-1.
                                                        z
Optionally, the sequence is scaled by the factor e .

The routine is derived from the routine CBESK in Amos [2].

Note: although the routine may not be called with (nu) less than
zero, for negative orders the formula K     (z)=K    (z) may be
                                       -(nu)     (nu)
used.

When N is greater than 1, extra values of K    (z) are computed
                                           (nu)
using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause
total loss of accuracy, and so no computation is performed. For
slightly smaller |z| or ((nu)+N-1), the computation is performed
but results are accurate to less than half of machine precision.
If |z| is very small, near the machine underflow threshold, or
((nu)+N-1) is too large, there is a risk of overflow and so no
computation is performed. In all the above cases, a warning is
given by the routine.

4. References

```

Functions. Dover Publications.

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: FNU -- DOUBLE PRECISION Input
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.

2: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the functions. Constraint: Z /= (0.0, 0.0).

3: N -- INTEGER Input
On entry: the number, N, of members required in the sequence $K_{(nu)}(z), K_{(nu)+1}(z),\ldots, K_{(nu)+N-1}(z)$. Constraint: N >= 1.

4: SCALE -- CHARACTER*1 Input
On entry: the scaling option.

If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the factor e^{z}. Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D)) array Output
On exit: the N required function values: CY(i) contains $K_{(nu)+i-1}(z)$, for i=1,2,...,N.

6: NZ -- INTEGER Output
On exit: the number of components of CY that are set to zero due to underflow. If NZ > 0 and Rez>=0.0, elements CY(1),CY(2),...,CY(NZ) are set to zero. If Rez<0.0, NZ simply states the number of underflows, and not which elements they are.

7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

```
6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry FNU < 0.0,

     or       Z = (0.0, 0.0),

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because ABS(Z) is less than a machine-dependent
     threshold value (given in the Users' Note for your
     implementation).

IFAIL= 3
     No computation has been performed due to the likelihood of
     overflow, because FNU + N - 1 is too large - how large
     depends on Z and the overflow threshold of the machine.

IFAIL= 4
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S18DCF are accurate to less
     than half of machine precision. This error exit may occur if
     either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).

IFAIL= 5
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S18DCF would be lost. This
     error exit may occur when either ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 6
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S18DCF would have caused overflow or
     underflow.
```

7. Accuracy

All constants in subroutine S18DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S18DCF, the actual number of correct digits is limited, in general, by p-s, where s~max(1,|log |z||,|log (nu)|) represents the number of digits
           10   10
lost due to the argument reduction. Thus the larger the values of |z| and (nu), the less the precision in the result. If S18DCF is called with N>1, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DCF with different base values of (nu) and different N, the computed values may not agree exactly. Empirical tests with modest values of (nu) and z have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S18DCF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S18DCF with N greater than 1, rather than to make N separate calls to S18DCF.

Paradoxically, for some values of z and (nu), it is cheaper to call S18DCF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is K (x) or K (x), i.e.,
                                      0   1
(nu)=0.0 or 1.0, where x is real and positive, and only a single function value is required, then it may be much cheaper to call S18ACF, S18ADF, S18CCF(*) or S18CDF(*), depending on whether a scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a

```
value for the order FNU, the second is a complex value for the
argument, Z, and the third is a value for the parameter SCALE.
The program calls the routine with N = 2 to evaluate the function
for orders FNU and FNU + 1, and it prints the results. The
process is repeated until the end of the input data stream is
encountered.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S18 -- Approximations of Special Functions                  S18DEF
        S18DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S18DEF returns a sequence of values for the modified Bessel
functions I      (z) for complex z, non-negative (nu) and
           (nu)+n
n=0,1,...,N-1, with an option for exponential scaling.

2. Specification

       SUBROUTINE S18DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
       INTEGER              N, NZ, IFAIL
       DOUBLE PRECISION     FNU
       COMPLEX(KIND(1.0D0)) Z, CY(N)
       CHARACTER*1          SCALE

3. Description

This subroutine evaluates a sequence of values for the modified
Bessel function I    (z), where z is complex, -(pi) < argz <=
                (nu)
(pi), and (nu) is the real, non-negative order. The N-member
sequence is generated for orders (nu), (nu)+1,...,(nu)+N-1.
                                                      -|Rez|
Optionally, the sequence is scaled by the factor e      .

The routine is derived from the routine CBESI in Amos [2].

Note: although the routine may not be called with (nu) less than
zero, for negative orders the formula
```

$$I_{-(nu)}(z) = I_{(nu)}(z) + \frac{2}{(pi)}\sin((pi)(nu))K_{(nu)}(z)$$

may be used (for the Bessel function $K_{(nu)}(z)$, see S18DCF).

When N is greater than 1, extra values of $I_{(nu)}(z)$ are computed using recurrence relations.

For very large |z| or ((nu)+N-1), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller |z| or ((nu)+N-1), the computation is performed but results are accurate to less than half of machine precision. If Re(z) is too large and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

[2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

5. Parameters

1: FNU -- DOUBLE PRECISION Input
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.

2: Z -- COMPLEX(KIND(1.0D0)) Input
On entry: the argument z of the functions.

3: N -- INTEGER Input
On entry: the number, N, of members required in the sequence $I_{(nu)}(z), I_{(nu)+1}(z), \ldots, I_{(nu)+N-1}(z)$. Constraint: N >= 1.

4: SCALE -- CHARACTER*1 Input
On entry: the scaling option.
If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the factor $e^{-|Rez|}$.

Constraint: SCALE = 'U' or 'S'.

```
 5:  CY(N) -- COMPLEX(KIND(1.0D)) array                    Output
     On exit: the N required function values: CY(i) contains
     I        (z), for i=1,2,...,N.
      (nu)+i-1

 6:  NZ -- INTEGER                                         Output
     On exit: the number of components of CY that are set to zero
     due to underflow.

     If NZ > 0, then elements CY(N-NZ+1),CY(N-NZ+2),...,CY(N) are
     set to zero.

 7:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry FNU < 0.0,

     or       N < 1,

     or       SCALE /= 'U' or 'S'.

IFAIL= 2
     No computation has been performed due to the likelihood of
     overflow, because real(Z) is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation). This error exit can only occur when
     SCALE = 'U'.

IFAIL= 3
     The computation has been performed, but the errors due to
     argument reduction in elementary functions make it likely
     that the results returned by S18DEF are accurate to less
     than half of machine precision. This error exit may occur
     when either ABS(Z) or FNU + N - 1 is greater than a machine-
     dependent threshold value (given in the Users' Note for
     your implementation).
```

```
IFAIL= 4
     No computation has been performed because the errors due to
     argument reduction in elementary functions mean that all
     precision in results returned by S18DEF would be lost. This
     error exit may occur when either ABS(Z) or FNU + N - 1 is
     greater than a machine-dependent threshold value (given in
     the Users' Note for your implementation).

IFAIL= 5
     No results are returned because the algorithm termination
     condition has not been met. This may occur because the
     parameters supplied to S18DEF would have caused overflow or
     underflow.

7. Accuracy

All constants in subroutine S18DEF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S18DEF, the actual
number of correct digits is limited, in general, by p-s, where
s~max(1,|log  |z||,|log  (nu)|) represents the number of digits
            10         10
lost due to the argument reduction. Thus the larger the values of
|z| and (nu), the less the precision in the result. If S18DEF is
called with N>1, then computation of function values via
recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are
computed by calls to S18DEF with different base values of (nu)
and different N, the computed values may not agree exactly.
Empirical tests with modest values of (nu) and z have shown that
the discrepancy is limited to the least significant 3-4 digits of
precision.

8. Further Comments

The time taken by the routine for a call of S18DEF is
approximately proportional to the value of N, plus a constant. In
general it is much cheaper to call S18DEF with N greater than 1,
rather than to make N separate calls to S18DEF.

Paradoxically, for some values of z and (nu), it is cheaper to
call S18DEF with a larger value of N than is required, and then
discard the extra function values returned. However, it is not
possible to state the precise circumstances in which this is
likely to occur. It is due to the fact that the base value used
to start recurrence may be calculated in different regions for
```

```
different N, and the costs in each region may differ greatly.

Note that if the function required is I (x) or I (x), i.e.,
                                       0        1
(nu)=0.0 or 1.0, where x is real and positive, and only a single
function value is required, then it may be much cheaper to call
S18AEF, S18AFF, S18CEF(*) or S18CFF(*), depending on whether a
scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read
sets of data from the input data stream. The first datum is a
value for the order FNU, the second is a complex value for the
argument, Z, and the third is a value for the parameter SCALE.
The program calls the routine with N = 2 to evaluate the function
for orders FNU and FNU + 1, and it prints the results. The
process is repeated until the end of the input data stream is
encountered.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S19 -- Approximations of Special Functions                 S19AAF
        S19AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S19AAF returns a value for the Kelvin function ber x via the
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S19AAF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Kelvin function
berx.
```

Note: ber(-x)=berx, so the approximation need only consider
x>=0.0.

The routine is based on several Chebyshev expansions:

For 0<=x<=5,

$$\text{berx} = \sum_{r=0}^{--'} a_r T_r(t) \text{ with } t = 2\left(\frac{x}{5}\right)^4 - 1;$$

For x>5,

$$\text{berx} = \frac{e^{x/\sqrt{2}}}{\sqrt{2\pi x}}\left[\left(1 + \frac{1}{-a(t)}\right)\cos(\alpha) + \frac{1}{-b(t)}\sin(\alpha)\right]$$

$$+ \frac{e^{-x/\sqrt{2}}}{\sqrt{2\pi x}}\left[\left(1 + \frac{1}{-c(t)}\right)\sin(\beta) + \frac{1}{-d(t)}\cos(\beta)\right]$$

$$\text{where } (\alpha) = \frac{x}{\sqrt{2}} - \frac{\pi}{8}, \quad (\beta) = \frac{x}{\sqrt{2}} + \frac{\pi}{8},$$

and a(t), b(t), c(t), and d(t) are expansions in the variable

$$t = \frac{10}{x} - 1.$$

When x is sufficiently close to zero, the result is set directly
to ber 0=1.0.

For large x, there is a danger of the result being totally
inaccurate, as the error amplification factor grows in an
essentially exponential manner; therefore the routine must fail.

4. References

```
      Functions. Dover Publications.

5. Parameters

 1:  X -- DOUBLE PRECISION                                    Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry ABS(X) is too large for an accurate result to be
     returned. On soft failure, the routine returns zero.

7. Accuracy

Since the function is oscillatory, the absolute error rather than
the relative error is important. Let E be the absolute error in
the result and (delta) be the relative error in the argument. If
(delta) is somewhat larger than the machine precision, then we
have:

                    |  x              |
                E~=| ---(ber x+bei x)|(delta)
                    |        1     1  |
                    | \/2             |

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the
absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

                             /   x   x/\/2
its amplitude grows like    /  -----e    . Therefore it is not
                          \/   2(pi)

possible to calculate the function with any accuracy when
```

```
    x/\/2  /2(pi)
\/xe     > -------. Note that this value of x is much smaller than
           (delta)

the minimum value of x for which the function overflows.

8. Further Comments

For details of the time taken by the routine see the Users' Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S19 -- Approximations of Special Functions                 S19ABF
        S19ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S19ABF returns a value for the Kelvin function bei x via the
routine name.

2. Specification

      DOUBLE PRECISION FUNCTION S19ABF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Kelvin function
beix.

Note: bei(-x)=beix, so the approximation need only consider
x>=0.0.
```

The routine is based on several Chebyshev expansions:

For 0<=x<=5,

$$\text{bei } x = \frac{x^2}{4} \sum_{r=0}^{\infty} {}' a_r T_r(t), \quad \text{with } t = 2\left(\frac{x}{5}\right)^4 - 1;$$

For x>5,

$$\text{bei } x = \frac{e^{x/\sqrt{2}}}{\sqrt{2\pi x}}\left[\left(1 - \frac{1}{a(t)}\right)\sin(\alpha) - \frac{b(t)}{x}\cos(\alpha)\right]$$

$$+ \frac{e^{x/\sqrt{2}}}{\sqrt{2\pi x}}\left[\left(1 - \frac{1}{c(t)}\right)\cos(\beta) - \frac{d(t)}{x}\sin(\beta)\right]$$

$$\text{where } \alpha = \frac{x}{\sqrt{2}} - \frac{\pi}{8}, \beta = \frac{x}{\sqrt{2}} + \frac{\pi}{8},$$

and a(t), b(t), c(t), and d(t) are expansions in the variable

$$t = \frac{10}{x} - 1.$$

When x is sufficiently close to zero, the result is computed as

$\text{bei } x = \frac{x^2}{4}$. If this result would underflow, the result returned is beix=0.0.

For large x, there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let E be the absolute error in the function, and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine precision, then we have:

$$\tilde{E} = \left| \frac{x}{\sqrt{2}} (-\mathrm{ber}\, x + \mathrm{bei}\, x) \right| (\mathrm{delta})$$

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and its amplitude grows like $\sqrt{\frac{e^{x/\sqrt{2}}}{2\pi}}$. Therefore it is

```
impossible to calculate the functions with any accuracy when

    x/\/2 /2(pi)
\/xe     > -------. Note that this value of x is much smaller than
           (delta)

the minimum value of x for which the function overflows.

8. Further Comments

S19 -- Approximations of Special Functions                 S19ACF
        S19ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S19ACF returns a value for the Kelvin function ker x, via the
routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S19ACF (X, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Kelvin function
ker x.

Note: for x<0 the function is undefined and at x=0 it is infinite
```

```
so we need only consider x>0.

The routine is based on several Chebyshev expansions:

For 0<x<=1,

                                (pi) 2
                ker x=-f(t)logx+ ----x g(t)+y(t)
                                 16

                                                                    4
where f(t), g(t) and y(t) are expansions in the variable t=2x -1;

For 1<x<=3,

                                (  11 )
                          ker x=exp(- --x)q(t)
                                (  16 )

where q(t) is an expansion in the variable t=x-2;

For x>3,

                      -x/\/2
              / (pi)       [(   1    )           1             ]
   ker x=   /  ----e       [(1+ -c(t))cos(beta)- -d(t)sin(beta)]
          \/    2x         [(   x    )           x             ]

                 x   (pi)
where (beta)= ---+ ----, and c(t) and d(t) are expansions in the
                   8
              \/2
             6
variable t= --1.
             x

When x is sufficiently close to zero, the result is computed as

                                                    2
                                ( x) (      3 2) x
                ker x=-(gamma)-log( -)+((pi)- -x ) --
                                ( 2) (      8  ) 16

and when x is even closer to zero, simply as
                    ( x)
ker x=-(gamma)-log( -).
                    ( 2)
```

```
                                                    / (pi) -x/\/2
For large x, ker x is asymptotically given by   /  ----e      and
                                              \/    2x

this becomes so small that it cannot be computed without
underflow and the routine fails.

4. References

[1]   Abramowitz M and Stegun I A (1968) Handbook of Mathematical
      Functions. Dover Publications.

5. Parameters

 1:  X -- DOUBLE PRECISION                                    Input
     On entry: the argument x of the function. Constraint: X > 0.

 2:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
     On entry X is too large, the result underflows. On soft
     failure, the routine returns zero.

IFAIL= 2
     On entry X <= 0, the function is undefined. On soft failure
     the routine returns zero.

7. Accuracy

Let E be the absolute error in the result, (epsilon) be the
relative error in the result and (delta) be the relative error in
the argument. If (delta) is somewhat larger than the machine
precision, then we have:

                   |  x               |
                E~=| ---(ker  x+kei x)|(delta),
                   |         1     1  |
```

```
                  | \/2             |

                      |     ker  x+kei x|
                      |  x      1     1 |
          (epsilon)~=| --- ------------|(delta).
                      |        ker x    |
                      | \/2             |
```

For very small x, the relative error amplification factor is approximately given by $\frac{1}{|\log x|}$, which implies a strong attenuation of relative error. However, (epsilon) in general cannot be less than the machine precision.

For small x, errors are damped by the function and hence are limited by the machine precision.

For medium and large x, the error behaviour, like the function itself, is oscillatory, and hence only the absolute accuracy for the function can be maintained. For this range of x, the

$$\text{amplitude of the absolute error decays like } \sqrt{\frac{\pi}{2}}\, e^{-x/\sqrt{2}}$$

which implies a strong attenuation of error. Eventually, ker x,

$$\text{which asymptotically behaves like } \sqrt{\frac{\pi}{2x}}\, e^{-x/\sqrt{2}}, \text{ becomes so}$$

small that it cannot be calculated without causing underflow, and the routine returns zero. Note that for large x the errors are dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

Underflow may occur for a few values of x close to the zeros of ker x, below the limit which causes a failure with IFAIL = 1.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

```
          Library software and should be available on-line.

          S19 -- Approximations of Special Functions                 S19ADF
                  S19ADF -- NAG Foundation Library Routine Document

          Note: Before using this routine, please read the Users' Note for
          your implementation to check implementation-dependent details.
          The symbol (*) after a NAG routine name denotes a routine that is
          not included in the Foundation Library.

          1. Purpose

          S19ADF returns a value for the Kelvin function keix via the
          routine name.

          2. Specification

                DOUBLE PRECISION FUNCTION S19ADF (X, IFAIL)
                INTEGER          IFAIL
                DOUBLE PRECISION X

          3. Description

          This routine evaluates an approximation to the Kelvin function
          keix.

          Note: for x<0 the function is undefined, so we need only consider
          x>=0.

          The routine is based on several Chebyshev expansions:

          For 0<=x<=1,

                                          2
                                 (pi)     x
                        keix=- ----f(t)+ --[-g(t)logx+v(t)]
                                  4       4

                                                                        4
          where f(t), g(t) and v(t) are expansions in the variable t=2x -1;

          For 1<x<=3,

                                        (  9 )
                                 keix=exp(- -x)u(t)
                                        (  8 )

          where u(t) is an expansion in the variable t=x-2;
```

For x>3,

$$keix = \sqrt{\frac{\pi}{2x}}\, e^{-x/\sqrt{2}}\left[\left(1+\frac{1}{x}\right)c(t)\sin(\beta) + \left(\frac{1}{x}\right)d(t)\cos(\beta)\right]$$

$$\text{where } \beta = \frac{x}{\sqrt{2}} + \frac{\pi}{8}, \text{ and } c(t) \text{ and } d(t) \text{ are expansions in the variable } t = \frac{6}{x}\sqrt{2}.$$

For x<0, the function is undefined, and hence the routine fails and returns zero.

When x is sufficiently close to zero, the result is computed as

$$keix = -\frac{\pi}{4}\left(1-\gamma-\log\left(\frac{x}{2}\right)\right)\frac{x^2}{4}$$

and when x is even closer to zero simply as

$$keix = -\frac{\pi}{4}.$$

For large x, keix is asymptotically given by $\sqrt{\frac{\pi}{2x}}\, e^{-x/\sqrt{2}}$ and this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function. Constraint: X >= 0.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry X is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2
On entry X < 0, the function is undefined. On soft failure the routine returns zero.

7. Accuracy

Let E be the absolute error in the result, and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine representation error, then we have:

```
   |  x                |
E~=| ---(-ker  x+kei x)|(delta).
   |          1     1  |
   | \/2               |
```

For small x, errors are attenuated by the function and hence are limited by the machine precision.

For medium and large x, the error behaviour, like the function itself, is oscillatory and hence only absolute accuracy of the function can be maintained. For this range of x, the amplitude of

```
                                / (pi)x -x/\/2
the absolute error decays like  /  -----e      , which implies a
                              \/     2
```

strong attenuation of error. Eventually, keix, which is

```
                                / (pi) -x/\/2
asymptotically given by   /  ----e      , becomes so small that it
                        \/    2x

cannot be calculated without causing underflow and therefore the
routine returns zero. Note that for large x, the errors are
dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

Underflow may occur for a few values of x close to the zeros of
keix, below the limit which causes a failure with IFAIL = 1.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S20 -- Approximations of Special Functions                S20ACF
        S20ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S20ACF returns a value for the Fresnel Integral S(x), via the
routine name.

2. Specification

      DOUBLE PRECISION FUNCTION S20ACF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Fresnel Integral

                           x
                           /   ( (pi) 2)
                    S(x)= |sin( ----t )dt.
```

$$\int_0^{\left(\frac{2}{x}\right)}$$

Note: S(x)=-S(-x), so the approximation need only consider x>=0.0

The routine is based on three Chebyshev expansions:

For 0<x<=3,

$$S(x)=x\sum_{r=0}^{3}{}' a_r T_r(t), \text{ with } t=2\left(\frac{x}{3}\right)^4-1;$$

For x>3,

$$S(x)=\frac{1}{2}\frac{f(x)}{x}\cos\left(\frac{\pi}{2}x^2\right)-\frac{g(x)}{x^3}\sin\left(\frac{\pi}{2}x^2\right),$$

$$\text{where } f(x)=\sum_{r=0}^{3}{}' b_r T_r(t),$$

$$\text{and } g(x)=\sum_{r=0}^{3}{}' c_r T_r(t), \text{ with } t=2\left(\frac{3}{x}\right)^4-1.$$

For small x, $S(x)\tilde{}=\frac{\pi}{6}x^3$. This approximation is used when x is sufficiently small for the result to be correct to machine precision. For very small x, this approximation would underflow; the result is then set exactly to zero.

For large x, $f(x)\tilde{}=\frac{1}{\pi}$ and $g(x)\tilde{}=\frac{1}{\pi^2}$. Therefore for moderately large x, when $\frac{1}{2^3\pi^3x^3}$ is negligible compared with $\frac{1}{2}$, the second term in the approximation for x>3 may be dropped. For very large x, when $\frac{1}{\pi x}$ becomes negligible, $S(x)\tilde{}=\frac{1}{2}$. However

there will be considerable difficulties in calculating
$\cos\left(\frac{(\pi)}{2}x\right)$ accurately before this final limiting value can be used. Since $\cos\left(\frac{(\pi)}{2}x\right)$ is periodic, its value is essentially determined by the fractional part of x^2. If $x = N+(\theta)$ where N is an integer and $0 \le (\theta) < 1$, then $\cos\left(\frac{(\pi)}{2}x\right)$ depends on (θ) and on N modulo 4. By exploiting this fact, it is possible to retain significance in the calculation of $\cos\left(\frac{(\pi)}{2}x\right)$ either all the way to the very large x limit, or at least until the integer part of $\frac{x}{2}$ is equal to the maximum integer allowed on the machine.

4. References

[1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

Let δ and ε be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e.,
if (delta) is due to data errors etc), then (epsilon) and (delta)
are approximately related by:

$$(\text{epsilon}) \tilde{=} \left| \frac{x \sin\left(\frac{(\text{pi})}{2} x\right)}{S(x)} \right| (\text{delta}).$$

Figure 1 shows the behaviour of the error amplification factor

$$\left| \frac{x \sin\left(\frac{(\text{pi})}{2} x\right)}{S(x)} \right|.$$

Figure 1
Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision,
then rounding errors could make (epsilon) slightly larger than
the above relation predicts.

For small x, (epsilon)~=3(delta) and hence there is only moderate
amplification of relative error. Of course for very small x where
the correct result would underflow and exact zero is returned,
relative error-control is lost.

For moderately large values of x,

$$|(\text{epsilon})| \tilde{=} \left| 2x \sin\left(\frac{(\text{pi})}{2} x\right) \right| |(\text{delta})|$$

and the result will be subject to increasingly large
amplification of errors. However the above relation breaks down
for large values of x (i.e., when $\frac{1}{x^2}$ is of the order of the
machine precision in this region the relative error in the result
is essentially bounded by $\frac{2}{(\text{pi})x}$).

Hence the effects of error amplification are limited and at worst

```
the relative error loss should not exceed half the possible
number of significant figures.

8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S20 -- Approximations of Special Functions                 S20ADF
        S20ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S20ADF returns a value for the Fresnel Integral C(x), via the
routine name.

2. Specification

      DOUBLE PRECISION FUNCTION S20ADF (X, IFAIL)
      INTEGER          IFAIL
      DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Fresnel Integral

                           x
                           /   ( (pi) 2)
                    C(x)= |cos( ----t )dt.
                           /   (  2    )
                           0

Note: C(x)=-C(-x), so the approximation need only consider x>=0.0

The routine is based on three Chebyshev expansions:
```

For 0<x<=3,

$$C(x)=x\sum_{r=0}^{\infty} a_r T_r(t), \text{ with } t=2\left(\frac{x}{3}\right)^4-1;$$

For x>3,

$$C(x)=\frac{1}{2}\frac{f(x)}{x}\sin\left(\frac{(\pi)}{2}x^4\right)-\frac{g(x)}{x^3}\cos\left(\frac{(\pi)}{2}x^4\right),$$

where $f(x)=\sum_{r=0}^{\infty} b_r T_r(t)$,

and $g(x)=\sum_{r=0}^{\infty} c_r T_r(t)$, with $t=2\left(\frac{3}{x}\right)^4-1$.

For small x, C(x)~=x. This approximation is used when x is sufficiently small for the result to be correct to machine precision.

For large x, $f(x)\sim=\frac{1}{(\pi)}$ and $g(x)\sim=\frac{1}{(\pi)^2}$. Therefore for moderately large x, when $\frac{1}{2^3(\pi)x^3}$ is negligible compared with $\frac{1}{2}$, the second term in the approximation for x>3 may be dropped. For very large x, when $\frac{1}{(\pi)x}$ becomes negligible, $C(x)\sim=\frac{1}{2}$. However there will be considerable difficulties in calculating $\sin\left(\frac{(\pi)}{2}x^4\right)$ accurately before this final limiting value can be used. Since $\sin\left(\frac{(\pi)}{2}x^4\right)$ is periodic, its value is essentially determined by the fractional part of x^4. If $x=N+(\text{theta})$, where N

```
                                        ( (pi) 2)
is an integer and 0<=(theta)<1, then sin( ----x ) depends on
                                        (  2    )
(theta) and on N modulo 4. By exploiting this fact, it is
possible to retain some significance in the calculation of
   ( (pi) 2)
sin( ----x ) either all the way to the very large x limit, or at
   (  2    )
                                  x
least until the integer part of   - is equal to the maximum
                                  2
integer allowed on the machine.

4. References

      Functions. Dover Publications.

5. Parameters

 1:  X -- DOUBLE PRECISION                                    Input
     On entry: the argument x of the function.

 2:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL
has been included for consistency with other routines in this
chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and result respectively.

If (delta) is somewhat larger than the machine precision (i.e if
(delta) is due to data errors etc), then (epsilon) and (delta)
are approximately related by:

                          |     ( (pi) 2)|
                          | xcos( ----x )|
                          |     (  2    )|
               (epsilon)~=| -------------|(delta).
```

```
                          |     C(x)     |
```

Figure 1 shows the behaviour of the error amplification factor

```
|     ( (pi) 2)|
| xcos( ----x )|
|     (  2    )|
| -------------|.
|     C(x)     |
```

Figure 1
Please see figure in printed Reference Manual

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon)~=(delta) and there is no amplification of relative error.

For moderately large values of x,

```
                          |     ( (pi) 2)|
            |(epsilon)|~=|2xcos( ----x )||(delta)|
                          |     (  2    )|
```

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down
for large values of x (i.e., when $\frac{1}{2x^2}$ is of the order of the machine precision); in this region the relative error in the result is essentially bounded by $\frac{2}{(\pi)x}$.

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

8. Further Comments

None.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

S21 -- Approximations of Special Functions                 S21BAF
        S21BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S21BAF returns a value of an elementary integral, which occurs as
a degenerate case of an elliptic integral of the first kind, via
the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S21BAF (X, Y, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X, Y

3. Description

This routine calculates an approximate value for the integral

                                 infty
                              1 /         dt
                    R (x,y)= - |     ----------
                     C       2 /
                               0     \/t+x(t+y)

where x>=0 and y/=0.

This function, which is related to the logarithm or inverse
hyperbolic functions for y<x and to inverse circular functions if
x<y, arises as a degenerate form of the elliptic integral of the
first kind. If y<0, the result computed is the Cauchy principal
value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to
reduce the arguments recursively towards their mean by the
system:

    x =x,
```

```
 0

y =y
 0

(mu) =(x +2y )/3,
    n   n   n

S =(y -x )/3(mu)
 n   n  n       n

(lambda) =y +2  /x y
        n  n  \/  n n

x   =(x +(lambda) )/4,
 n+1   n         n

y   =(y +(lambda) )/4.
 n+1   n         n
```

The quantity $|S_n|$ for n=0,1,2,3,... decreases with increasing n, eventually $|S_n| \tilde{} 1/4$. For small enough S_n the required function value can be approximated by the first few terms of the Taylor series about the mean. That is

$$R_C(x,y) = \left(1 + \frac{3S_n}{10} + \frac{S_n^2}{7} + \frac{3S_n^3}{8} + \frac{9S_n^4}{22}\right) / \sqrt{\mu_n}\,.$$

The truncation error involved in using this approximation is bounded by $16|S_n|^6/(1-2|S_n|)$ and the recursive process is stopped when S_n is small enough for this truncation error to be negligible compared to the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the

result is done before returning to the calling program.

4. References

[2] Carlson B C (1978) Computing Elliptic Integrals by Duplication. (Preprint) Department of Physics, Iowa State University.

[3] Carlson B C (1988) A Table of Elliptic Integrals of the Third Kind. Math. Comput. 51 267--280.

5. Parameters

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input
On entry: the arguments x and y of the function, respectively. Constraint: X >= 0.0 and Y /= 0.0.

3: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry X < 0.0; the function is undefined.

IFAIL= 2
On entryY = 0.0; the function is undefined.

On soft failure the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be

```
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the
relationship of this function to the classical definitions of the
elliptic integrals.

9. Example

This example program simply generates a small set of non-extreme
arguments which are used with the routine to produce the table of
low accuracy results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

S21 -- Approximations of Special Functions                S21BBF
        S21BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S21BBF returns a value of the symmetrised elliptic integral of
the first kind, via the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S21BBF (X, Y, Z, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X, Y, Z

3. Description

This routine calculates an approximation to the integral

                           infty
                         1 /            dt
               R (x,y,z)= - |     -----------------
                F         2 /
```

```
                              0     \/(t+x)(t+y)(t+z)
```

where x, y, z>=0 and at most one is zero.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

```
     x =min(x,y,z),z =max(x,y,z),
      0             0

     y = remaining third intermediate value argument.
      0
```

(This ordering, which is possible because of the symmetry of the function, is done for technical reasons related to the avoidance of overflow and underflow.)

```
    (mu) =   (x +y +3z )/3
        n      n  n   n

    X    =   (1-x )/(mu)
     n           n      n

    Y    =   (1-y )/(mu)
     n           n      n

    Z    =   (1-z )/(mu)
     n           n      n

    (lambda) =  /x y +  /y z +  /z x
           n \/  n n /  n n /  n n

    x    =   (x +(lambda) )/4
     n+1       n         n

    y    =   (y +(lambda) )/4
     n+1       n         n

    z    =   (z +(lambda) )/4
     n+1       n         n
```

(epsilon) =max(|X |,|Y |,|Z |) and the function may be approximated adequately by a 5th order power series:

```
        n       n    n    n

                                 (        2           )
                                 (   E    E   3E E    E )
                           1     (    2   2    2 3    3)
```

$$R_F(x,y,z) = \frac{1}{2\sqrt{\mu_n}}\left(1 - \frac{10}{24} + \frac{44}{44} - \frac{14}{}\right)$$

where $E_2 = X_n Y_n + Y_n Z_n + Z_n X_n$, $E_3 = X_n Y_n Z_n$.

The truncation error involved in using this approximation is bounded by $(\text{epsilon})^6/4(1-(\text{epsilon})^3)$ and the recursive process is stopped when this truncation error is negligible compared with the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

[3] Carlson B C (1988) A Table of Elliptic Integrals of the Third Kind. Math. Comput. 51 267--280.

5. Parameters

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input

3: Z -- DOUBLE PRECISION Input
On entry: the arguments x, y and z of the function.
Constraint: X, Y, Z >= 0.0 and only one of X, Y and Z may be zero.

4: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

```
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry one or more of X, Y and Z is negative; the function
     is undefined.

IFAIL= 2
     On entry two or more of X, Y and Z are zero; the function is
     undefined.

     On soft failure, the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will
result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the
relationship of this function to the classical definitions of the
elliptic integrals.

If two arguments are equal, the function reduces to the
elementary integral R , computed by S21BAF.
                      C

9. Example

This example program simply generates a small set of non-extreme
arguments which are used with the routine to produce the table of
low accuracy results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

%%

S21 -- Approximations of Special Functions S21BCF
S21BCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BCF returns a value of the symmetrised elliptic integral of the second kind, via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S21BCF (X, Y, Z, IFAIL)
INTEGER          IFAIL
DOUBLE PRECISION X, Y, Z
```

3. Description

This routine calculates an approximate value for the integral

$$R_D(x,y,z) = \frac{3}{2}\int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}}$$

where x, y>=0, at most one of x and y is zero, and z>0.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$x_0 = x$$

$$y_0 = y$$

$$z_0 = z$$

$$(\mu)_n = (x_n + y_n + 3z_n)/5$$

$$X_n = (1-x_n)/(\mu_n)$$

$$Y_n = (1-y_n)/(\mu_n)$$

$$Z_n = (1-z_n)/(\mu_n)$$

$$(\lambda) = \sqrt{x_n y_n + y_n z_n + z_n x_n}$$

$$x_{n+1} = (x_n + (\lambda))/4$$

$$y_{n+1} = (y_n + (\lambda))/4$$

$$z_{n+1} = (z_n + (\lambda))/4$$

For n sufficiently large,

$$(\epsilon)_n = \max(|X_n|,|Y_n|,|Z_n|)^{(-)^{(n+1)}/4}$$

and the function may be approximated adequately by a 5th order power series

$$R_D(x,y,z) = 3 \sum_{m=0}^{n-1} \frac{4^{-m}}{(z_n + (\lambda))^m \sqrt{z_n}^m}$$

$$\frac{4^{-n}}{\sqrt{(\mu)_n^3}}\left[1 + \frac{3}{7n}S_n^{(2)} + \frac{1}{3n}S_n^{(3)} + \frac{3}{22n}S_n^{(2)2} + \frac{3}{11n}S_n^{(4)} + \frac{3}{13n}S_n^{(2)}S_n^{(3)} + \frac{3}{n}S_n^{(5)} + \frac{3}{13n}S_n^{(6)}\right]$$

where

$$S_n^{(m)} = (X_n^m + Y_n^m + 3Z_n^m)/2m.$$

```
                    n   ( n  n   n)

The truncation error in this expansion is bounded by
              6
     3(epsilon)
              n
 ------------------- and the recursive process is terminated when

    /             3
   / (1-(epsilon) )
 \/             n
this quantity is negligible compared with the machine precision.

The routine may fail either because it has been called with
arguments outside the domain of definition, or with arguments so
extreme that there is an unavoidable danger of setting underflow
or overflow.

                -3/2
Note: R (x,x,x)=x    , so there exists a region of extreme
       D
arguments for which the function value is not representable.

     Constraint: X, Y >= 0.0, Z > 0.0 and only one of X and Y may
     be zero.

 4:  IFAIL -- INTEGER                                 Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
```

```
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry either X or Y is negative, or both X and Y are
     zero; the function is undefined.

IFAIL= 2
     On entry Z <= 0.0; the function is undefined.

IFAIL= 3
     On entry either Z is too close to zero or both X and Y are
     too close to zero: there is a danger of setting overflow.

IFAIL= 4
     On entry at least one of X, Y and Z is too large: there is a
     danger of setting underflow.

     On soft failure the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will
result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

S21 -- Approximations of Special Functions                 S21BDF
        S21BDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S21BDF returns a value of the symmetrised elliptic integral of
the third kind, via the routine name.

2. Specification

       DOUBLE PRECISION FUNCTION S21BDF (X, Y, Z, R, IFAIL)
       INTEGER          IFAIL
       DOUBLE PRECISION X, Y, Z, R

3. Description

This routine calculates an approximation to the integral

                         infty
                       3 /                 dt
       R (x,y,z,(rho))= - |     -------------------------
        J               2 /
                         0     (t+(rho))\/(t+x)(t+y)(t+z)

where x, y, z>=0, (rho)/=0 and at most one of x, y and z is zero.

If p<0, the result computed is the Cauchy principal value of the
integral.

The basic algorithm, which is due to Carlson [2] and [3], is to
reduce the arguments recursively towards their mean by the rule:

    x    =   x
     0

    y    =   y
     0
```

```
z    =   z
 0

(rho) =  (rho)
     0

(mu) =   (x +y +z +2(rho) )/5
    n      n  n  n       n

X    =   (1-x )/(mu)
 n           n      n

Y    =   (1-y )/(mu)
 n           n      n

Z    =   (1-z )/(mu)
 n           n      n

P    =   (1-(rho) )/(mu)
 n               n      n

(lambda) =   /x y +  /y z +  /z x
          n\/  n n /  n n /  n n

x    =   (x +(lambda) )/4
 n+1       n         n

y    =   (y +(lambda) )/4
 n+1       n         n

z    =   (z +(lambda) )/4
 n+1       n         n

(rho) =  ((rho) +(lambda) )/4
     n+1       n         n
                                          2
          [                              ]
(alpha) =[(rho) (  /x +  /y +  /z )+  /x y z ]
       n [     n \/  n /  n /  n  /  n n n]

                                     2
(beta) = (rho) ((rho) +(lambda) )
      n       n      n         n
```

For n sufficiently large,

```
                                                 1
          (epsilon) =max(|X |,|Y |,|Z |,|P |)~ --
```

```
                      n       n    n    n    n     n
                                                 4
```

and the function may be approximated by a 5th order power series

```
                  n-1
                  --  -m
R (x,y,z,(rho))=3 >  4  R ((alpha) ,(beta) )
 J                --     C        m       m
                  m=0
```

```
      -n
     4     [   3 (2)  1 (3)  3   (2) 2  3  (4)  3  (2) (3)  3  (5)]
+ ---------[1+ -S   + -S   + --(S   ) + --S   + --S   S   + --S   ]
           [   7 n    3 n    22  n      11 n    13 n   n    13 n  ]
     /    3
    / (mu)
  \/      n
```

```
       (m)     m  m  m   m
where S    = (X +Y +Z +2P )/2m.
       n       n  n  n   n
```

The truncation error in this expansion is bounded by

```
          6    /              3
3(epsilon) /  / (1-(epsilon) )  and the recursion process is
          n \/              n
```

terminated when this quantity is negligible compared with the machine precision. The routine may fail either because it has been called with arguments outside the domain of definition or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

```
                    3
                  - -
                    2
```

Note: R (x,x,x,x)=x , so there exists a region of extreme
J
arguments for which the function value is not representable.

      Third Kind. Math. Comput. 51 267--280.

5. Parameters

 1:  X -- DOUBLE PRECISION                                    Input

 2:  Y -- DOUBLE PRECISION                                    Input

 3:  Z -- DOUBLE PRECISION                                    Input

 4:  R -- DOUBLE PRECISION                                    Input
     On entry: the arguments x, y, z and (rho) of the function.
     Constraint: X, Y, Z >= 0.0, R /= 0.0 and at most one of X, Y
     and Z may be zero.

 5:  IFAIL -- INTEGER                                  Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
     On entry at least one of X, Y and Z is negative, or at least
     two of them are zero; the function is undefined.

IFAIL= 2
     On entry R = 0.0; the function is undefined.

IFAIL= 3
     On entry either R is too close to zero, or any two of X, Y
     and Z are too close to zero; there is a danger of setting
     overflow.

IFAIL= 4
     On entry at least one of X, Y, Z and R is too large; there
     is a danger of setting underflow.

IFAIL= 5
```

```
     An error has occurred in a call to S21BAF. Any such
     occurrence should be reported to NAG.

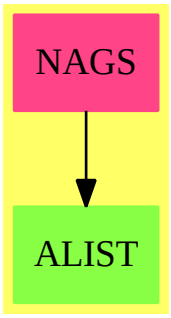
     On soft failure, the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will
result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the
relationship of this function to the classical definitions of the
elliptic integrals.



If the argument R is equal to any of the other arguments, the
function reduces to the integral R , computed by S21BCF.
                                  D

9. Example

This example program simply generates a small set of non-extreme
arguments which are used with the routine to produce the table of
low accuracy results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

s18adf : (DoubleFloat,Integer) -> Result
 ++ s18adf(x,ifail)
 ++ returns the value of the modified Bessel Function
 ++  K (x), via the routine name.
 ++   1
 ++ See \downlink{Manual Page}{manpageXXs18adf}.
s18aef : (DoubleFloat,Integer) -> Result
 ++ s18aef(x,ifail)
 ++ returns the value of the modified Bessel Function
 ++  I (x), via the routine name.
 ++   0
 ++ See \downlink{Manual Page}{manpageXXs18aef}.
s18aff : (DoubleFloat,Integer) -> Result
 ++ s18aff(x,ifail)
 ++ returns a value for the modified Bessel Function
 ++  I (x), via the routine name.
 ++   1
 ++ See \downlink{Manual Page}{manpageXXs18aff}.
s18dcf : (DoubleFloat,Complex DoubleFloat,Integer,String,_
    Integer) -> Result
 ++ s18dcf(fnu,z,n,scale,ifail)
 ++ returns a sequence of values for the modified Bessel functions
 ++  K      (z) for complex z, non-negative (nu) and
 ++   (nu)+n
 ++ n=0,1,...,N-1, with an option for exponential scaling.
 ++ See \downlink{Manual Page}{manpageXXs18dcf}.
s18def : (DoubleFloat,Complex DoubleFloat,Integer,String,_
    Integer) -> Result
 ++ s18def(fnu,z,n,scale,ifail)
 ++ returns a sequence of values for the modified Bessel functions
 ++  I      (z) for complex z, non-negative (nu) and
 ++   (nu)+n
```

```
 ++ n=0,1,...,N-1, with an option for exponential scaling.
 ++ See \downlink{Manual Page}{manpageXXs18def}.
s19aaf : (DoubleFloat,Integer) -> Result
 ++ s19aaf(x,ifail)
 ++ returns a value for the Kelvin function ber(x) via the
 ++ routine name.
 ++ See \downlink{Manual Page}{manpageXXs19aaf}.
s19abf : (DoubleFloat,Integer) -> Result
 ++ s19abf(x,ifail)
 ++ returns a value for the Kelvin function bei(x) via the
 ++ routine name.
 ++ See \downlink{Manual Page}{manpageXXs19abf}.
s19acf : (DoubleFloat,Integer) -> Result
 ++ s19acf(x,ifail)
 ++ returns a value for the Kelvin function ker(x), via the
 ++ routine name.
 ++ See \downlink{Manual Page}{manpageXXs19acf}.
s19adf : (DoubleFloat,Integer) -> Result
 ++ s19adf(x,ifail)
 ++ returns a value for the Kelvin function kei(x) via the
 ++ routine name.
 ++ See \downlink{Manual Page}{manpageXXs19adf}.
s20acf : (DoubleFloat,Integer) -> Result
 ++ s20acf(x,ifail)
 ++ returns a value for the Fresnel Integral S(x), via the
 ++ routine name.
 ++ See \downlink{Manual Page}{manpageXXs20acf}.
s20adf : (DoubleFloat,Integer) -> Result
 ++ s20adf(x,ifail)
 ++ returns a value for the Fresnel Integral C(x), via the
 ++ routine name.
 ++ See \downlink{Manual Page}{manpageXXs20adf}.
s21baf : (DoubleFloat,DoubleFloat,Integer) -> Result
 ++ s21baf(x,y,ifail)
 ++ returns a value of an elementary integral, which occurs as
 ++ a degenerate case of an elliptic integral of the first kind, via
 ++ the routine name.
 ++ See \downlink{Manual Page}{manpageXXs21baf}.
s21bbf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
 ++ s21bbf(x,y,z,ifail)
 ++ returns a value of the symmetrised elliptic integral of
 ++ the first kind, via the routine name.
 ++ See \downlink{Manual Page}{manpageXXs21bbf}.
s21bcf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
 ++ s21bcf(x,y,z,ifail)
 ++ returns a value of the symmetrised elliptic integral of
 ++ the second kind, via the routine name.
 ++ See \downlink{Manual Page}{manpageXXs21bcf}.
s21bdf : (DoubleFloat,DoubleFloat,DoubleFloat,DoubleFloat,_
    Integer) -> Result
```

```
    ++ s21bdf(x,y,z,r,ifail)
    ++ returns a value of the symmetrised elliptic integral of
    ++ the third kind, via the routine name.
    ++ See \downlink{Manual Page}{manpageXXs21bdf}.

++ Keywords:
++ References:
++ Description:
++ This package lifts a mapping from coefficient rings R to S to
++ a mapping from sparse univariate polynomial over R to
++ a sparse univariate polynomial over S.
++ Note that the mapping is assumed
++ to send zero to zero, since it will only be applied to the non-zero
++ coefficients of the polynomial.

NewSparseUnivariatePolynomialFunctions2(R:Ring, S:Ring): with
  map:(R->S,NewSparseUnivariatePolynomial R) -> NewSparseUnivariatePolynomial S
    ++ \axiom{map(func, poly)} creates a new polynomial by applying func to
    ++ every non-zero coefficient of the polynomial poly.

++ Also See: FunctionFieldIntegralBasis, WildFunctionFieldIntegralBasis
++ AMS Classifications:
++ Keywords: number field, integral basis, discriminant
++ Examples:
++ References:
++ Description:
++ In this package F is a framed algebra over the integers (typically
++ \spad{F = Z[a]} for some algebraic integer a).  The package provides
++ functions to compute the integral closure of Z in the quotient
++ quotient field of F.

NumberFieldIntegralBasis(UP,F): Exports == Implementation where
  UP : UnivariatePolynomialCategory Integer
  F  : FramedAlgebra(Integer,UP)

  FR  ==> Factored Integer
  I   ==> Integer
  Mat ==> Matrix I
  NNI ==> NonNegativeInteger
  Ans ==> Record(basis: Mat, basisDen: I, basisInv:Mat,discr: I)
```

```
Exports ==> with
  discriminant: () -> Integer
    ++ \spad{discriminant()} returns the discriminant of the integral
    ++ closure of Z in the quotient field of the framed algebra F.
  integralBasis : () -> Record(basis: Mat, basisDen: I, basisInv:Mat)
    ++ \spad{integralBasis()} returns a record
    ++ \spad{[basis,basisDen,basisInv]}
    ++ containing information regarding the integral closure of Z in the
    ++ quotient field of F, where F is a framed algebra with Z-module
    ++ basis \spad{w1,w2,...,wn}.
    ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
    ++ the \spad{i}th element of the integral basis is
    ++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
    ++ \spad{i}th row of \spad{basis} contains the coordinates of the
    ++ \spad{i}th basis vector.  Similarly, the \spad{i}th row of the
    ++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
    ++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
    ++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
    ++ \spad{wi = sum(bij * vj, j = 1..n)}.
  localIntegralBasis : I -> Record(basis: Mat, basisDen: I, basisInv:Mat)
    ++ \spad{integralBasis(p)} returns a record
    ++ \spad{[basis,basisDen,basisInv]} containing information regarding
    ++ the local integral closure of Z at the prime \spad{p} in the quotient
    ++ field of F, where F is a framed algebra with Z-module basis
    ++ \spad{w1,w2,...,wn}.
    ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
    ++ the \spad{i}th element of the integral basis is
    ++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
    ++ \spad{i}th row of \spad{basis} contains the coordinates of the

++ Author: Yurij Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Basic Operations:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package is a suite of functions for the numerical integration of an
++ ordinary differential equation of n variables:\br
++ \tab{5}dy/dx = f(y,x)\tab{5}y is an n-vector\br
++ All the routines are based on a 4-th order Runge-Kutta kernel.
++ These routines generally have as arguments:\br
++ n, the number of dependent variables;\br
++ x1, the initial point;\br
++ h, the step size;\br
++ y, a vector of initial conditions of length n\br
++ which upon exit contains the solution at \spad{x1 + h};\br
++
++ \spad{derivs}, a function which computes the right hand side of the
++ ordinary differential equation: \spad{derivs(dydx,y,x)} computes
++ \spad{dydx}, a vector which contains the derivative information.
++
++ In order of increasing complexity:\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} advances the solution vector to\br
++ \tab{5}\spad{x1 + h} and return the values in y.\br
++
++ \tab{5}\spad{rk4(y,n,x1,h,derivs,t1,t2,t3,t4)} is the same as\br
++ \tab{5}\spad{rk4(y,n,x1,h,derivs)} except that you must provide 4 scratch\br
++ \tab{5}arrays t1-t4 of size n.\br
++
++ \tab{5}Starting with y at x1, \spad{rk4f(y,n,x1,x2,ns,derivs)}\br
++ \tab{5}uses \spad{ns} fixed steps of a 4-th order Runge-Kutta\br
++ \tab{5}integrator to advance the solution vector to x2 and return\br
++ \tab{5}the values in y.  Argument x2, is the final point, and\br
++ \tab{5}\spad{ns}, the number of steps to take.
++
++ \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} takes a 5-th order
++ Runge-Kutta step with monitoring of local truncation to ensure
++ accuracy and adjust stepsize.
++ The function takes two half steps and one full step and scales
++ the difference in solutions at the final point. If the error is
++ within \spad{eps}, the step is taken and the result is returned.
++ If the error is not within \spad{eps}, the stepsize if decreased
++ and the procedure is tried again until the desired accuracy is
++ reached. Upon input, an trial step size must be given and upon
++ return, an estimate of the next step size to use is returned as
```

```
++ well as the step size which produced the desired accuracy.
++ The scaled error is computed as\br
++ \tab{5}\spad{error = MAX(ABS((y2steps(i) - y1step(i))/yscal(i)))}\br
++ and this is compared against \spad{eps}. If this is greater
++ than \spad{eps}, the step size is reduced accordingly to\br
++ \tab{5}\spad{hnew = 0.9 * hdid * (error/eps)**(-1/4)}\br
++ If the error criterion is satisfied, then we check if the
++ step size was too fine and return a more efficient one. If
++ \spad{error > \spad{eps} * (6.0E-04)} then the next step size should be\br
++ \tab{5}\spad{hnext = 0.9 * hdid * (error/\spad{eps})**(-1/5)}\br
++ Otherwise \spad{hnext = 4.0 * hdid} is returned.
++ A more detailed discussion of this and related topics can be
++ found in the book "Numerical Recipies" by W.Press, B.P. Flannery,
++ S.A. Teukolsky, W.T. Vetterling published by Cambridge University Press.
++
++ Argument \spad{step} is a record of 3 floating point
++ numbers \spad{(try , did , next)},
++ \spad{eps} is the required accuracy,
++ \spad{yscal} is the scaling vector for the difference in solutions.
++ On input, \spad{step.try} should be the guess at a step
++ size to achieve the accuracy.
++ On output, \spad{step.did} contains the step size which achieved the
++ accuracy and \spad{step.next} is the next step size to use.
++
++ \spad{rk4qc(y,n,x1,step,eps,yscal,derivs,t1,t2,t3,t4,t5,t6,t7)} is the
++ same as \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} except that the user
++ must provide the 7 scratch arrays \spad{t1-t7} of size n.
++
++ \spad{rk4a(y,n,x1,x2,eps,h,ns,derivs)}
++ is a driver program which uses \spad{rk4qc} to integrate n ordinary
++ differential equations starting at x1 to x2, keeping the local
++ truncation error to within \spad{eps} by changing the local step size.
++ The scaling vector is defined as\br
++ \tab{5}\spad{yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny}\br
++ where \spad{y(i)} is the solution at location x, \spad{dydx} is the
++ ordinary differential equation's right hand side, h is the current
++ step size and \spad{tiny} is 10 times the
++ smallest positive number representable.
++
++ The user must supply an estimate for a trial step size and
++ the maximum number of calls to \spad{rk4qc} to use.
++ Argument x2 is the final point,
++ \spad{eps} is local truncation,
++ \spad{ns} is the maximum number of call to \spad{rk4qc} to use.

++ References:
++ Description:
++ This suite of routines performs numerical quadrature using
++ algorithms derived from the basic trapezoidal rule. Because
++ the error term of this rule contains only even powers of the
++ step size (for open and closed versions), fast convergence
++ can be obtained if the integrand is sufficiently smooth.
++
++ Each routine returns a Record of type TrapAns, which contains
++ value Float: estimate of the integral
++ error Float: estimate of the error in the computation
++ totalpts Integer: total number of function evaluations
++ success Boolean: if the integral was computed within the user
++ specified error criterion
++ To produce this estimate, each routine generates an internal
++ sequence of sub-estimates, denoted by S(i), depending on the
++ routine, to which the various convergence criteria are applied.
++ The user must supply a relative accuracy, \spad{eps_r}, and an absolute
++ accuracy, \spad{eps_a}. Convergence is obtained when either\br
++ \tab{5}\spad{ABS(S(i) - S(i-1)) < eps_r * ABS(S(i-1))}\br
++ \tab{5}or \spad{ABS(S(i) - S(i-1)) < eps_a}
++ are true statements.
++
++ The routines come in three families and three flavors:
++ closed: romberg, simpson, trapezoidal
++ open: rombergo, simpsono, trapezoidalo
++ adaptive closed: aromberg, asimpson, atrapezoidal
++
++ The S(i) for the trapezoidal family is the value of the
++ integral using an equally spaced absicca trapezoidal rule for
++ that level of refinement.
++
++ The S(i) for the simpson family is the value of the integral
++ using an equally spaced absicca simpson rule for that level of
++ refinement.
++
++ The S(i) for the romberg family is the estimate of the integral
++ using an equally spaced absicca romberg method. For
++ the i-th level, this is an appropriate combination of all the
++ previous trapezodial estimates so that the error term starts
++ with the 2*(i+1) power only.
++
++ The three families come in a closed version, where the formulas
++ include the endpoints, an open version where the formulas do not
++ include the endpoints and an adaptive version, where the user
++ is required to input the number of subintervals over which the
++ appropriate closed family integrator will apply with the usual
++ convergence parmeters for each subinterval. This is useful
++ where a large number of points are needed only in a small fraction
++ of the entire domain.
```

```
++
++ Each routine takes as arguments:\br
++ f integrand\br
++ a starting point\br
++ b ending point\br
++ eps_r relative error\br
++ eps_a absolute error\br
++ nmin refinement level when to start checking for convergence (> 1)\br
++ nmax maximum level of refinement\br
++
++ The adaptive routines take as an additional parameter,
++ nint, the number of independent intervals to apply a closed
++ family integrator of the same name.
++
++ Notes:\br
++ Closed family level i uses \spad{1 + 2**i} points.\br
++ Open family level i uses \spad{1 + 3**i} points.\br

++ Keywords:
++ References:
++ Description:
++ \spadtype{OpenMathServerPackage} provides the necessary
++ operations to run AXIOM as an OpenMath server, reading/writing objects
++ to/from a port.  Please note the facilities available here are very basic.
++ The idea is that a user calls e.g. \axiom{Omserve(4000,60)} and then
++ another process sends OpenMath objects to port 4000 and reads the result.

OpenMathServerPackage(): with
  OMreceive : OpenMathConnection -> Any
  ++ OMreceive(c) reads an OpenMath object from connection \axiom{c} and
  ++ returns the appropriate AXIOM object.
  OMsend    : (OpenMathConnection, Any) -> Void
  ++ OMsend(c,u) attempts to output \axiom{u} on \axiom{c} in OpenMath.
  OMserve   : (SingleInteger, SingleInteger) -> Void
  ++ OMserve(portnum,timeout) puts AXIOM into server mode on port number
  ++ \axiom{portnum}.  The parameter \axiom{timeout} specifies the timeout
  ++ period for the connection.
```

Exports ==>  with
  homogenize: (PolyRing,Integer) -> PolyRing

  interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing)

  fullDesTree: () -> Void

  fullInfClsPt: () -> Void

  setCurve: PolyRing -> PolyRing

  projectivePoint: List K -> ProjPt

  pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

  placesAbove: ProjPt -> List Plc

  setSingularPoints: List ProjPt -> List ProjPt

  goppaCode: (DIVISOR,DIVISOR) -> Matrix K

  goppaCode: (DIVISOR,List(Plc)) -> Matrix K

  rationalPlaces: () -> List Plc
    ++ rationalPlaces returns all the rational places of  the
    ++ curve defined by the polynomial given to the package.

  theCurve: () -> PolyRing
    ++ theCurve returns the specified polynomial for the package.

  genus: () -> NNI
    ++ genus returns the genus of the curve defined by the polynomial
    ++ given to the package.

  genusNeg: () -> Integer

  desingTreeWoFullParam  : () -> List DesTree
    ++ desingTreeWoFullParam returns the desingularisation trees at all
```

```
    ++ singular points of the curve defined by the polynomial given to
    ++ the package. The local parametrizations are not computed.

  desingTree: () -> List DesTree
    ++ desingTree returns the desingularisation trees at all singular
    ++ points of the curve defined by the polynomial given to the package.

  rationalPoints: () -> List(ProjPt)

  singularPoints: () -> List(ProjPt)
    ++ rationalPoints() returns the singular points of the
    ++ curve defined by the polynomial given to the package.
    ++ If the singular points lie in an extension of the specified
    ++ ground field an error message is issued specifying the extension
    ++ degree needed to find all singular points.

  parametrize: (PolyRing,Plc) -> PCS
   ++ parametrize(f,pl) returns a local parametrization of f at the place pl.

  lBasis: (DIVISOR,NNI) -> List FRACPOLY

  lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
    ++ lBasis computes a basis associated to the specified divisor

  findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
    Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

  interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
    ++ interpolateForms(d,n) returns a basis of the interpolate forms of
    ++ degree n of the divisor d.

  eval: (PolyRing,Plc) -> K
    ++ eval(f,pl) evaluate f at the place pl.

  eval: (PolyRing,PolyRing,Plc) -> K
    ++ eval(f,g,pl) evaluate the function f/g at the place pl.

  eval: (FRACPOLY,Plc) -> K
    ++ eval(u,pl) evaluate the function u at the place pl.

  evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
    ++ evalIfCan(f,pl) evaluate f at the place pl
    ++ (returns "failed" if it is a pole).

  evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
    ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
    ++ (returns "failed" if it is a pole).

  evalIfCan: (FRACPOLY,Plc) -> Union(K,"failed")
    ++ evalIfCan(u,pl) evaluate the function u at the place pl
```

```
      ++ (returns "failed" if it is a pole).

    intersectionDivisor: PolyRing -> DIVISOR
      ++ intersectionDivisor(pol) compute the intersection divisor (the
      ++ Cartier divisor) of the form pol with the curve. If some
      ++ intersection points lie in an extension of the ground field,
      ++ an error message is issued specifying the extension degree
      ++ needed to find all the intersection points.
      ++ (If pol is not homogeneous an error message is issued).

    adjunctionDivisor: () -> DIVISOR
      ++ adjunctionDivisor computes the adjunction divisor of the plane
      ++ curve given by the polynomial set with the function setCurve.

    if K has Finite then --should we say LocallyAlgebraicallyClosedField??

      LPolynomial: () -> SparseUnivariatePolynomial Integer
        ++ Returns the L-Polynomial of the curve.

      LPolynomial: PI -> SparseUnivariatePolynomial Integer
        ++ LPolynomial(d) returns the L-Polynomial of the curve in
        ++ constant field extension of degree d.

      classNumber: () -> Integer
        ++ Returns the class number of the curve.

      placesOfDegree: PI -> List Plc
        ++ placesOfDegree(d) returns all places of degree d of the curve.

      numberOfPlacesOfDegree: PI -> Integer
        ++ returns the number of places of the given degree

      numberRatPlacesExtDeg: PI -> Integer
        ++ numberRatPlacesExtDeg(n) returns the number of rational
        ++ places in the constant field extenstion of degree n

      numberPlacesDegExtDeg: (PI, PI) -> Integer
        ++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
        ++ places of degree d in the constant field extension of degree n

      ZetaFunction: () -> UTSZ
        ++ Returns the Zeta function of the curve. Calculated by
        ++ using the L-Polynomial

      ZetaFunction: PI -> UTSZ
        ++ Returns the Zeta function of the curve in constant field
        ++ extension. Calculated by using the L-Polynomial

    placesAbove: ProjPt -> List Plc

    projectivePoint: List DK -> ProjPt

    setSingularPoints: List ProjPt -> List ProjPt
```

```
rationalPlaces: () -> List Plc
  ++ rationalPlaces returns all the rational places of  the
  ++ curve defined by the polynomial given to the package.

theCurve: () -> PolyRing
  ++ theCurve returns the specified polynomial for the package.

genus: () -> NNI
  ++ genus returns the genus of the curve defined by the polynomial
  ++ given to the package.

genusNeg: () -> Integer

desingTreeWoFullParam  : () -> List DesTree
  ++ desingTreeWoFullParam returns the desingularisation trees at all
  ++ singular points of the curve defined by the polynomial given to
  ++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
  ++ desingTree returns the desingularisation trees at all singular points
  ++ of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)

singularPoints: () -> List(ProjPt)
  ++ rationalPoints() returns the singular points of the
  ++ curve defined by the polynomial given to the package.
  ++ If the singular points lie in an extension of the specified
  ++ ground field an error message is issued specifying the extension
  ++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
 ++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FracPoly

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _
  Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing2)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
```

```
      ++ eval(f,pl) evaluate f at the place pl.

    eval: (PolyRing,PolyRing,Plc) -> K
      ++ eval(f,g,pl) evaluate the function f/g at the place pl.

    eval: (FracPoly,Plc) -> K
      ++ eval(u,pl) evaluate the function u at the place pl.

    evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
      ++ evalIfCan(f,pl) evaluate f at the place pl
      ++ (returns "failed" if it is a pole).

    evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
      ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
      ++ (returns "failed" if it is a pole).

    evalIfCan: (FracPoly,Plc) -> Union(K,"failed")
      ++ evalIfCan(u,pl) evaluate the function u at the place pl
      ++ (returns "failed" if it is a pole).

    intersectionDivisor: PolyRing -> DIVISOR
      ++ intersectionDivisor(pol) compute the intersection divisor  of the
      ++ form pol with the curve.
      ++ (If pol is not homogeneous an error message is issued).

    adjunctionDivisor: () -> DIVISOR
      ++ adjunctionDivisor computes the adjunction divisor of the plane
      ++ curve given by the polynomial defined by setCurve.

    if DK has Finite then --should we say LocallyAlgebraicallyClosedField??

      LPolynomial: () -> SparseUnivariatePolynomial Integer
        ++ Returns the L-Polynomial of the curve.

      LPolynomial: PI -> SparseUnivariatePolynomial Integer
        ++ LPolynomial(d) returns the L-Polynomial of the curve in
++ constant field extension of degree d.

      classNumber: () -> Integer
        ++ Returns the class number of the curve.

      placesOfDegree: PI -> List Plc
        ++ placesOfDegree(d) returns all places of degree d of the
++ curve.

      numberOfPlacesOfDegree: PI -> Integer
        ++ returns the number of places of the given degree

      numberRatPlacesExtDeg: PI -> Integer
        ++ numberRatPlacesExtDeg(n) returns the number of rational
```

```
++ places in the constant field extenstion of degree n

++ Description:
++ In this package K is a finite field, R is a ring of univariate
++ polynomials over K, and F is a monogenic algebra over R.
++ We require that F is monogenic, i.e. that \spad{F = K[x,y]/(f(x,y))},
++ because the integral basis algorithm used will factor the polynomial
++ \spad{f(x,y)}.  The package provides a function to compute the integral
++ closure of R in the quotient field of F as well as a function to compute
++ a "local integral basis" at a specific prime.

```
-- modified to conform with new runtime system 06/04/90
-- updated with comments for MB, 02/16/94
-- also cleaned up some unnecessary arguments in regime routine
--
-- MB: In order to allow the rhs to be indeterminate, while working
-- mainly with the parametric variables on the lhs (less number of
-- variables), certain conversions of internal representation from
-- GR to Polynomial R and Fraction Polynomial R are done.  At the time
-- of implementation, I thought that this may be more efficient.  I
-- have not done any comparison since that requires rewriting the
-- package.  My own application needs to call this package quite often,
-- and most computations involves only polynomials in the parametric
-- variables.
```

```
-- The 12 modes of psolve are probably not all necessary.  Again, I
-- was thinking that if there are many regimes and many ranks, then
-- the output is quite big, and it may be nice to be able to save it
-- and read the results in later to continue computing rather than
-- recomputing.  Because of the combinatorial nature of the algorithm
-- (computing all subdeterminants!), it does not take a very big matrix
-- to get into many regimes.  But I now have second thoughts of this
-- design, since most of the time, the results are just intermediate,
-- passed to be further processed.  On the other hand, there is probably
-- no penalty in leaving the options as is.
```

— package PLEQN ParametricLinearEquations —

```
)abbrev package PLEQN ParametricLinearEquations
++ Author: William Sit, spring 89
++ Description:
++ This package completely solves a parametric linear system of equations
++ by decomposing the set of all parametric values for which the linear
++ system is consistent into a union of quasi-algebraic  sets (which need
++ not be irredundant, but most of the time is). Each quasi-algebraic
++ set is described by a list of polynomials that vanish on the set, and
++ a list of polynomials that vanish at no point of the set.
++ For each quasi-algebraic set, the solution of the linear system
++ is given, as a particular solution and  a basis of the homogeneous
++ system.
++
++ The parametric linear system should be given in matrix form, with
++ a coefficient matrix and a right hand side vector. The entries
++ of the coefficient matrix and right hand side vector should be
++ polynomials in the parametric variables, over a Euclidean domain
++ of characteristic zero.
++
++ If the system is homogeneous, the right hand side need not be given.
++ The right hand side can also be  replaced by an indeterminate vector,
++ in which case, the conditions required for consistency will also be
++ given.
++
++ The package has other facilities for saving results to external
++ files, as well as solving the system for a specified minimum rank.
++ Altogether there are 12 mode maps for psolve, as explained below.

-- MB: The following macros are data structures to store mostly
-- intermediate results
-- Rec stores a subdeterminant with corresponding row and column indices
-- Fgb is a Groebner basis for the ideal generated by the subdeterminants
--     of a given rank.
-- Linsys specifies a linearly independent system of a given system
--     assuming a given rank, using given row and column indices
-- Linsoln stores the solution to the parametric linear system as a basis
--     and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
--     and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
--     given by a list of equations (eqzro) and one inequation (neqzro)
--     describing the quasi-algebraic set which is the regime; the
--     additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
--     of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve.  On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
```

```
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

bsolve: (M GR, L GF, NNI, S, Inputmode) -> Ranksolns
  ++ bsolve(c, w, r, s, m) returns a list of regimes and
  ++ solutions of the system c z = w for ranks at least r;
  ++ depending on the mode m chosen, it writes the output to
  ++ a file given by the string s.
dmp2rfi: GR -> GF
  ++ dmp2rfi(p) converts p to target domain
dmp2rfi: M GR -> M GF
  ++ dmp2rfi(m) converts m to target domain
dmp2rfi: L GR -> L GF
  ++ dmp2rfi(l) converts l to target domain
se2rfi:  L Symbol -> L GF
  ++ se2rfi(l) converts l to target domain
```

```
      pr2dmp: PR -> GR
        ++ pr2dmp(p) converts p to target domain
      hasoln: (Fgb, L GR) -> Rec8
        ++ hasoln(g, l) tests whether the quasi-algebraic set
        ++ defined by p = 0 for p in g and q ^= 0 for q in l
        ++ is empty or not and returns a simplified definition
        ++ of the quasi-algebraic set
        -- this is now done in QALGSET package
      ParCondList: (M GR,NNI) -> RankConds
        ++ ParCondList(c,r) computes a list of subdeterminants of each
        ++ rank >= r of the matrix c and returns
        ++ a groebner basis for the
        ++ ideal they generate
      redpps: (Linsoln, Fgb) -> Linsoln
        ++ redpps(s,g) returns the simplified form of s after reducing
        ++ modulo a groebner basis g

--              L O C A L    F U N C T I O N S

      B1solve: Linsys -> Linsoln
        ++ B1solve(s) solves the system (s.mat) z = s.vec
        ++ for the variables given by the column indices of s.cols
        ++ in terms of the other variables and the right hand side s.vec
        ++ by assuming that the rank is s.rank,
        ++ that the system is consistent, with the linearly
        ++ independent equations indexed by the given row indices s.rows;
        ++ the coefficients in s.mat involving parameters are treated as
        ++ polynomials.  B1solve(s) returns a particular solution to the
        ++ system and a basis of the homogeneous system (s.mat) z = 0.
      factorset: GR -> L GR
        ++ factorset(p) returns the set of irreducible factors of p.
      maxrank: RankConds -> NNI
        ++ maxrank(r) returns the maximum rank in the list r of regimes
      minrank: RankConds -> NNI
        ++ minrank(r) returns the minimum rank in the list r of regimes
      minset: L L GR -> L L GR
        ++ minset(sl) returns the sublist of sl consisting of the minimal
        ++ lists (with respect to inclusion) in the list sl of lists
      nextSublist: (I, I) -> L L I
        ++ nextSublist(n,k) returns a list of k-subsets of {1, ..., n}.
      overset?: (L GR, L L GR) -> Boolean
        ++ overset?(s,sl) returns true if s properly a sublist of a member
        ++ of sl; otherwise it returns false
      ParCond    : (M GR,NNI) -> Eqns
        ++ ParCond(m,k) returns the list of all k by k subdeterminants in
        ++ the matrix m
      redmat: (M GR, Fgb) -> M GR
        ++ redmat(m,g) returns a matrix whose entries are those of m
```

```
      ++ modulo the ideal generated by the groebner basis g
    regime: (Rec,M GR,L GF,L L GR,NNI,NNI,Inputmode) -> Rec3
      ++ regime(y,c, w, p, r, rm, m) returns a regime,
      ++ a list of polynomials specifying the consistency conditions,
      ++ a particular solution and basis representing the general
      ++ solution of the parametric linear system c z = w
      ++ on that regime. The regime returned depends on
      ++ the subdeterminant y.det and the row and column indices.
      ++ The solutions are simplified using the assumption that
      ++ the system has rank r and maximum rank rm. The list p
      ++ represents a list of list of factors of polynomials in
      ++ a groebner basis of the ideal generated by higher order
      ++ subdeterminants, and ius used for the simplification.
      ++ The mode m
      ++ distinguishes the cases when the system is homogeneous,
      ++ or the right hand side is arbitrary, or when there is no
      ++ new right hand side variables.
    sqfree: GR -> GR
      ++ sqfree(p) returns the product of square free factors of p
    inconsistent?: L GR -> Boolean
      ++ inconsistant?(pl) returns true if the system of equations
      ++ p = 0 for p in pl is inconsistent.  It is assumed
      ++ that pl is a groebner basis.
      -- this is needed because of change to
      -- EuclideanGroebnerBasisPackage
    inconsistent?: L PR -> Boolean
      ++ inconsistant?(pl) returns true if the system of equations
      ++ p = 0 for p in pl is inconsistent.  It is assumed
      ++ that pl is a groebner basis.
      -- this is needed because of change to
      -- EuclideanGroebnerBasisPackage

```
=======================================================================
PartialFractionPackage examples
=======================================================================

When Axiom is given an expression such as:

  a:=x+1/(y+1)

it will end up with the result in Fraction Polynomial Integer.

        x y + x + 1
        -----------
           y + 1

We might want it in a partial fraction form. This can be done with:

  partialFraction(a,y)$PFRPAC(INT)

              1
        x + -----
            y + 1

We can do the same thing with a different variable:

  b:=y+1/(x+1)

        (x + 1)y + 1
        ------------
            x + 1

  partialFraction(b,x)$PFRPAC(INT)

              1
```

```
        y + -----
            x + 1

++ Related Domains:
++ Also See:
++ AMS Classifications:
++ Keywords: partition, permutation
++ References:
++ Description:
++ PartitionsAndPermutations contains functions for generating streams of
++ integer partitions, and streams of sequences of integers
++ composed from a multi-set.

PartitionsAndPermutations: Exports == Implementation where
  I   ==> Integer
  L   ==> List
  ST  ==> Stream
  ST1 ==> StreamFunctions1
  ST2 ==> StreamFunctions2
  ST3 ==> StreamFunctions3

  Exports ==> with

    partitions: (I,I,I) -> ST L I
      ++\spad{partitions(p,l,n)} is the stream of partitions
```

```
    ++ of n whose number of parts is no greater than p
    ++ and whose largest part is no greater than l.
  partitions: I -> ST L I
    ++\spad{partitions(n)} is the stream of all partitions of n.
  partitions: (I,I) -> ST L I
    ++\spad{partitions(p,l)} is the stream of all
    ++ partitions whose number of
    ++ parts and largest part are no greater than p and l.
  conjugate: L I -> L I
    ++\spad{conjugate(pt)} is the conjugate of the partition pt.
  conjugates: ST L I -> ST L I
    ++\spad{conjugates(lp)} is the stream of conjugates of a stream
    ++ of partitions lp.
  shuffle: (L I,L I) -> ST L I
    ++\spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
    ++ and l2, i.e. all sequences that can be formed from
    ++ merging l1 and l2.
  shufflein: (L I,ST L I) -> ST L I
    ++\spad{shufflein(l,st)} maps shuffle(l,u) on to all
    ++ members u of st, concatenating the results.
  sequences: (L I,L I) -> ST L I
    ++\spad{sequences(l1,l2)} is the stream of all sequences that
    ++ can be composed from the multiset defined from
    ++ two lists of integers l1 and l2.
    ++ For example,the pair \spad{([1,2,4],[2,3,5])} represents
    ++ multi-set with 1 \spad{2}, 2 \spad{3}'s, and 4 \spad{5}'s.
  sequences: L I -> ST L I
    ++ \spad{sequences([l0,l1,l2,..,ln])} is the set of
    ++  all sequences formed from
    ++ \spad{l0} 0's,\spad{l1} 1's,\spad{l2} 2's,...,\spad{ln} n's.
  permutations: I -> ST L I
    ++\spad{permutations(n)} is the stream of permutations
    ++ formed from \spad{1,2,3,...,n}.

17.24 package PMPLCAT PatternMatchPolynomialCategory

17.24.1 PatternMatchPolynomialCategory (PMPLCAT)

Exports:
patternMatch

— package PMPLCAT PatternMatchPolynomialCategory —

```
)abbrev package PMPLCAT PatternMatchPolynomialCategory
++ Author: Manuel Bronstein
++ Date Created: 9 Jan 1990
++ Date Last Updated: 20 June 1991
++ Keywords: pattern, matching, polynomial.
++ Description:
++ This package provides pattern matching functions on polynomials.

PatternMatchPolynomialCategory(S,E,V,R,P):Exports== Implementation where
  S: SetCategory
  E: OrderedAbelianMonoidSup
  V: OrderedSet
  R: Join(Ring, OrderedSet, PatternMatchable S)
  P: Join(PolynomialCategory(R, E, V), ConvertibleTo Pattern S)

  N   ==> NonNegativeInteger
  PAT ==> Pattern S
  PRS ==> PatternMatchResult(S, P)
  RCP ==> Record(val:PAT, exponent:N)
  RCX ==> Record(var:V, exponent:N)

  Exports ==> with
    patternMatch: (P, PAT, PRS, (V, PAT, PRS) -> PRS) -> PRS
      ++ patternMatch(p, pat, res, vmatch) matches the pattern pat to
      ++ the polynomial p. res contains the variables of pat which
      ++ are already matched and their matches; vmatch is the matching
      ++ function to use on the variables.
      -- This can be more efficient than pushing down when the variables
      -- are recursive over P (e.g. kernels)
    if V has PatternMatchable S then
      patternMatch: (P, PAT, PRS) -> PRS
        ++ patternMatch(p, pat, res) matches the pattern pat to

========================================================================
Permanent examples
========================================================================

The package Permanent provides the function permanent for square
matrices.  The permanent of a square matrix can be computed in the
same way as the determinant by expansion of minors except that for the
permanent the sign for each element is 1, rather than being 1 if the
row plus column indices is positive and -1 otherwise.  This function
is much more difficult to compute efficiently than the determinant.
An example of the use of permanent is the calculation of the n-th
derangement number, defined to be the number of different possibilities
for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere.
Think of the rows as one-half of each couple (for example, the males) and
the columns the other half.  The permanent of such a matrix gives the
desired derangement number.

  kn n ==
    r : MATRIX INT := new(n,n,1)
    for i in 1..n repeat
      r.i.i := 0
    r

Here are some derangement numbers, which you see grow quite fast.

  permanent(kn(5) :: SQMATRIX(5,INT))

  [permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]

++ Description:
++ Permanent implements the functions permanent, the
++ permanent for square matrices.

Permanent(n : PositiveInteger, R : Ring with commutative("*")):
 public == private where
  I  ==> Integer
  L  ==> List
  V  ==> Vector
  SM  ==> SquareMatrix(n,R)
  VECTPKG1 ==> VectorPackage1(I)
  NNI ==> NonNegativeInteger
  PI ==> PositiveInteger
  GRAY ==> GrayCode
```

```
public ==> with

  permanent:  SM  -> R
    ++ permanent(x) computes the permanent of a square matrix x.
    ++ The permanent is equivalent to
    ++ the \spadfun{determinant} except that coefficients have
    ++ no change of sign. This function
    ++ is much more difficult to compute than the
    ++ determinant. The formula used is by H.J. Ryser,
    ++ improved by [Nijenhuis and Wilf, Ch. 19].
    ++ Note that permanent(x) choose one of three algorithms, depending
    ++ on the underlying ring R and on n, the number of rows (and
    ++ columns) of x:\br
    ++ if 2 has an inverse in R we can use the algorithm of
    ++ [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
    ++ some modifications are necessary:\br
    ++ if n > 6 and R is an integral domain with characteristic
    ++ different from 2 (the algorithm works if and only 2 is not a
    ++ zero-divisor of R and characteristic()$R ^= 2,
    ++ but how to check that for any given R ?),
    ++ the local function permanent2 is called;\br
    ++ else, the local function permanent3 is called
    ++ (works for all commutative rings R).

++ References:
++ Description:
++ Groebner functions for P F
++ This package is an interface package to the groebner basis
++ package which allows you to compute groebner bases for polynomials
++ in either lexicographic ordering or total degree ordering refined
++ by reverse lex. The input is the ordinary polynomial type which
++ is internally converted to a type with the required ordering.
++ The resulting grobner basis is converted back to ordinary polynomials.
++ The ordering among the variables is controlled by an explicit list
++ of variables which is passed as a second argument. The coefficient
++ domain is allowed to be any gcd domain, but the groebner basis is
++ computed as if the polynomials were over a field.

  Exports ==> with
```

```
    variables   : F -> List V
      ++ variables(f) returns the list of variables appearing
      ++ in the numerator or the denominator of f.
    mainVariable: F -> Union(V, "failed")
      ++ mainVariable(f) returns the highest variable appearing
      ++ in the numerator or the denominator of f, "failed" if
      ++ f has no variables.
    univariate  : (F, V) -> RF
      ++ univariate(f, v) returns f viewed as a univariate
      ++ rational function in v.
    multivariate: (RF, V) -> F
      ++ multivariate(f, v) applies both the numerator and
      ++ denominator of f to v.
    univariate  : (F, V, UP) -> UP
      ++ univariate(f, x, p) returns f viewed as a univariate
      ++ polynomial in x, using the side-condition \spad{p(x) = 0}.
    isPlus      : F -> Union(List F, "failed")
      ++ isPlus(p) returns [m1,...,mn] if \spad{p = m1 + ... + mn} and
      ++ \spad{n > 1}, "failed" otherwise.
    isTimes     : F -> Union(List F, "failed")
      ++ isTimes(p) returns \spad{[a1,...,an]} if
      ++ \spad{p = a1 ... an} and \spad{n > 1},
      ++ "failed" otherwise.
    isExpt      : F -> Union(Record(var:V, exponent:Integer), "failed")
      ++ isExpt(p) returns \spad{[x, n]} if \spad{p = x**n} and \spad{n <> 0},
      ++ "failed" otherwise.
    isPower     : F -> Union(Record(val:F, exponent:Integer), "failed")
      ++ isPower(p) returns \spad{[x, n]} if \spad{p = x**n} and \spad{n <> 0},
      ++ "failed" otherwise.

      ++ \axiom{unprotectedRemoveRedundantFactors(p,q)} returns the same as
      ++ \axiom{removeRedundantFactors(p,q)} but does assume that neither
      ++ \axiom{p} nor \axiom{q} lie in the base ring \axiom{R} and assumes that
      ++ \axiom{infRittWu?(p,q)} holds. Moreover, if \axiom{R} is gcd-domain,
      ++ then \axiom{p} and \axiom{q} are assumed to be square free.
   removeRedundantFactors: (LP,P) -> LP
      ++ \axiom{removeRedundantFactors(lp,q)} returns the same as
      ++ \axiom{removeRedundantFactors(cons(q,lp))} assuming
      ++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
      ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
      ++ by some some polynomial \axiom{qj} associated to \axiom{pj}.
   removeRedundantFactors : (LP,LP) -> LP
      ++ \axiom{removeRedundantFactors(lp,lq)} returns the same as
      ++ \axiom{removeRedundantFactors(concat(lp,lq))} assuming
      ++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
      ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
      ++ by some polynomial \axiom{qj} associated to \axiom{pj}.
   removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
      ++ \axiom{removeRedundantFactors(lp,lq,remOp)} returns the same as
      ++ \axiom{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)}
      ++ assuming that \axiom{remOp(lq)} returns \axiom{lq} up to similarity.
   certainlySubVariety? : (LP,LP) -> B
```

```
   ++ \axiom{certainlySubVariety?(newlp,lp)} returns true iff for every \axiom{p}
   ++ in \axiom{lp} the remainder of \axiom{p} by \axiom{newlp} using the division algorith
   ++ of Groebner techniques is zero.
possiblyNewVariety? : (LP, List LP) -> B
   ++ \axiom{possiblyNewVariety?(newlp,llp)} returns true iff for every \axiom{lp}
   ++ in \axiom{llp} certainlySubVariety?(newlp,lp) does not hold.
probablyZeroDim?: LP -> B
   ++ \axiom{probablyZeroDim?(lp)} returns true iff the number of polynomials
   ++ in \axiom{lp} is not smaller than the number of variables occurring
   ++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{selectPolynomials(pred?,ps)} returns \axiom{gps,bps} where
   ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
   ++ such that \axiom{pred?(p)} holds and \axiom{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{selectOrPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
   ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
   ++ such that \axiom{pred?(p)} holds for some \axiom{pred?} in \axiom{lpred?}
   ++ and \axiom{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{selectAndPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
   ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
   ++ such that \axiom{pred?(p)} holds for every \axiom{pred?} in \axiom{lpred?}
   ++ and \axiom{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{quasiMonicPolynomials(lp)} returns \axiom{qmps,nqmps} where
   ++ \axiom{qmps} is a list of the quasi-monic polynomials in \axiom{lp}
   ++ and \axiom{nqmps} are the other ones.
univariate? : P -> B
   ++ \axiom{univariate?(p)} returns true iff \axiom{p} involves one and
   ++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{univariatePolynomials(lp)} returns \axiom{ups,nups} where
   ++ \axiom{ups} is a list of the univariate polynomials,
   ++ and \axiom{nups} are the other ones.
linear? : P -> B
   ++ \axiom{linear?(p)} returns true iff \axiom{p} does not lie
   ++ in the base ring \axiom{R} and has main degree \axiom{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{linearPolynomials(lp)} returns \axiom{lps,nlps} where
   ++ \axiom{lps} is a list of the linear polynomials in lp,
   ++ and  \axiom{nlps} are the other ones.
bivariate? : P -> B
   ++ \axiom{bivariate?(p)} returns true iff \axiom{p} involves two and
   ++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
   ++ \axiom{bivariatePolynomials(lp)} returns \axiom{bps,nbps} where
   ++ \axiom{bps} is a list of the bivariate polynomials,
   ++ and \axiom{nbps} are the other ones.
removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP
```

```
      ++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)} returns
      ++ \axiom{newlp}where \axiom{newlp} is obtained from \axiom{lp}
      ++ by removing in every polynomial \axiom{p} of \axiom{lp}
      ++ any occurence of a polynomial \axiom{f} in \axiom{lf}.
      ++ This may involve a lot of exact-quotients computations.
    removeRoughlyRedundantFactorsInPols : (LP, LP,B) -> LP
      ++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf,opt)} returns
      ++ the same as \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)}
      ++ if \axiom{opt} is \axiom{false} and if the previous operation
      ++ does not return any non null and constant polynomial,
      ++ else return \axiom{[1]}.
    removeRoughlyRedundantFactorsInPol : (P,LP) -> P
      ++ \axiom{removeRoughlyRedundantFactorsInPol(p,lf)} returns the same as
      ++ removeRoughlyRedundantFactorsInPols([p],lf,true)
    interReduce: LP -> LP
      ++ \axiom{interReduce(lp)} returns \axiom{lq} such that \axiom{lp}
      ++ and \axiom{lq} generate the same ideal and no polynomial
      ++ in \axiom{lq} is reducuble by the others in the sense
      ++ of Groebner bases. Since no assumptions are required
      ++ the result may depend on the ordering the reductions are
      ++ performed.
    roughBasicSet: LP -> Union(Record(bas:T,top:LP),"failed")
      ++ \axiom{roughBasicSet(lp)} returns the smallest (with Ritt-Wu
      ++ ordering) triangular set contained in \axiom{lp}.
    crushedSet: LP -> LP
      ++ \axiom{crushedSet(lp)} returns \axiom{lq} such that \axiom{lp} and
      ++ and \axiom{lq} generate the same ideal and no rough basic
      ++ sets reduce (in the sense of Groebner bases) the other
      ++ polynomials in \axiom{lq}.
    rewriteSetByReducingWithParticularGenerators : (LP,(P->B),((P,P)->B),((P,P)->P)) -> LP
      ++ \axiom{rewriteSetByReducingWithParticularGenerators(lp,pred?,redOp?,redOp)}
      ++ returns \axiom{lq} where \axiom{lq} is computed by the following
      ++ algorithm. Chose a basic set w.r.t. the reduction-test \axiom{redOp?}
      ++ among the polynomials satisfying property \axiom{pred?},
      ++ if it is empty then leave, else reduce the other polynomials by
      ++ this basic set w.r.t. the reduction-operation \axiom{redOp}.
      ++ Repeat while another basic set with smaller rank can be computed.
      ++ See code. If \axiom{pred?} is \axiom{quasiMonic?} the ideal is unchanged.
    rewriteIdealWithQuasiMonicGenerators : (LP,((P,P)->B),((P,P)->P)) -> LP
      ++ \axiom{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
      ++ \axiom{lq} where \axiom{lq} and \axiom{lp} generate
      ++ the same ideal in \axiom{R^(-1) P} and \axiom{lq}
      ++ has rank not higher than the one of \axiom{lp}.
      ++ Moreover, \axiom{lq} is computed by reducing \axiom{lp}
      ++ w.r.t. some basic set of the ideal generated by
      ++ the quasi-monic polynomials in \axiom{lp}.
    if R has GcdDomain
    then
      squareFreeFactors : P -> LP
        ++ \axiom{squareFreeFactors(p)} returns the square-free factors of \axiom{p}
```

```
      ++ over \axiom{R}
    univariatePolynomialsGcds : LP -> LP
      ++ \axiom{univariatePolynomialsGcds(lp)} returns \axiom{lg} where
      ++ \axiom{lg} is a list of the gcds of every pair in \axiom{lp}
      ++ of univariate polynomials in the same main variable.
    univariatePolynomialsGcds : (LP,B) -> LP
      ++ \axiom{univariatePolynomialsGcds(lp,opt)} returns the same as
      ++ \axiom{univariatePolynomialsGcds(lp)} if \axiom{opt} is
      ++ \axiom{false} and if the previous operation does not return
      ++ any non null and constant polynomial, else return \axiom{[1]}.
    removeRoughlyRedundantFactorsInContents : (LP, LP) -> LP
      ++ \axiom{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
      ++ \axiom{newlp}where \axiom{newlp} is obtained from \axiom{lp}
      ++ by removing in the content of every polynomial of \axiom{lp}
      ++ any occurence of a polynomial \axiom{f} in \axiom{lf}. Moreover,
      ++ squares over \axiom{R} are first removed in the content
      ++ of every polynomial of \axiom{lp}.
    removeRedundantFactorsInContents : (LP, LP) -> LP
      ++ \axiom{removeRedundantFactorsInContents(lp,lf)} returns \axiom{newlp}
      ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
      ++ in the content of every polynomial of \axiom{lp} any non trivial
      ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
      ++ squares over \axiom{R} are first removed in the content
      ++ of every polynomial of \axiom{lp}.
    removeRedundantFactorsInPols : (LP, LP) -> LP
      ++ \axiom{removeRedundantFactorsInPols(lp,lf)} returns \axiom{newlp}
      ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
      ++ in every polynomial \axiom{p} of \axiom{lp} any non trivial
      ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
      ++ squares over \axiom{R} are first removed in every
      ++ polynomial \axiom{lp}.
  if (R has EuclideanDomain) and (R has CharacteristicZero)
  then
    irreducibleFactors : LP -> LP
      ++ \axiom{irreducibleFactors(lp)} returns \axiom{lf} such that if
      ++ \axiom{lp = [p1,...,pn]} and \axiom{lf = [f1,...,fm]} then
      ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
      ++ are irreducible over \axiom{R} and are pairwise distinct.
    lazyIrreducibleFactors : LP -> LP
      ++ \axiom{lazyIrreducibleFactors(lp)} returns \axiom{lf} such that if
      ++ \axiom{lp = [p1,...,pn]} and \axiom{lf = [f1,...,fm]} then
      ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{fi}
      ++ are irreducible over \axiom{R} and are pairwise distinct.
      ++ The algorithm tries to avoid factorization into irreducible
      ++ factors as far as possible and makes previously use of gcd
      ++ techniques over \axiom{R}.
    removeIrreducibleRedundantFactors : (LP, LP) -> LP
      ++ \axiom{removeIrreducibleRedundantFactors(lp,lq)} returns the same
      ++ as \axiom{irreducibleFactors(concat(lp,lq))} assuming
      ++ that \axiom{irreducibleFactors(lp)} returns \axiom{lp}
```

```
        ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
        ++ by some polynomial \axiom{qj} associated to \axiom{pj}.

++ Date Last Updated: November 1993, (P.Gianni)
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package computes square-free decomposition of multivariate
++ polynomials over a coefficient ring which is an arbitrary gcd domain.
++ The requirement on the coefficient domain guarantees that the
++ \spadfun{content} can be
++ removed so that factors will be primitive as well as square-free.
++ Over an infinite ring of finite characteristic,it may not be possible to
++ guarantee that the factors are square-free.
```

  denomRicDE: L -> UP
    ++ denomRicDE(op) returns a polynomial \spad{d} such that any rational
    ++ solution of the associated Riccati equation of \spad{op y = 0} is
    ++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
    ++ and a reduced r. Also, \spad{deg(p) < deg(d)} and {gcd(d,q) = 1}.
  leadingCoefficientRicDE:  L -> List REC
    ++ leadingCoefficientRicDE(op) returns
    ++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
    ++ part of any rational solution of the associated Riccati equation of
    ++ \spad{op y = 0} must have degree mj for some j, and its leading
    ++ coefficient is then a zero of pj. In addition,\spad{m1>m2> ... >mk}.
  constantCoefficientRicDE: (L, UP -> List F) -> List CNT
    ++ constantCoefficientRicDE(op, ric) returns
    ++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
    ++ solution with no polynomial part of the associated Riccati equation of
    ++ \spad{op y = 0} must be one of the ai's in which case the equation for
    ++ \spad{z = y e^{-int ai}} is \spad{Li z = 0}.
    ++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
    ++ is the associated linear equation.
  polyRicDE: (L, UP -> List F) -> List POL
    ++ polyRicDE(op, zeros) returns
    ++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
    ++ part of any rational solution of the associated Riccati equation of
    ++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
    ++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z =0}.
    ++ \spad{zeros} is a zero finder in \spad{UP}.
  singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
    ++ singRicDE(op, zeros, ezfactor) returns
    ++ \spad{[[f1, L1], [f2, L2], ... , [fk, Lk]]} such that the singular
    ++ part of any rational solution of the associated Riccati equation of
    ++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
    ++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z=0}.
    ++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
    ++ \spad{H(x,P_i(x)) = 0 modulo C(x)}.
    ++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
    ++ not necessarily into irreducibles.
  changeVar: (L, UP) -> L
    ++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.
```

```
    changeVar: (L, RF) -> L
      ++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.

17.68 package PSEUDLIN PseudoLinearNormalForm

17.68.1 PseudoLinearNormalForm (PSEUDLIN)

Exports:
changeBase companionBlocks normalForm

— **package PSEUDLIN PseudoLinearNormalForm** —

```
)abbrev package PSEUDLIN PseudoLinearNormalForm
++ Author: Bruno Zuercher
++ Date Created: November 1993
++ Date Last Updated: 12 April 1994
++ Description:
++ PseudoLinearNormalForm provides a function for computing a block-companion
++ form for pseudo-linear operators.

PseudoLinearNormalForm(K:Field): Exports == Implementation where
  ER  ==> Record(C: Matrix K, g: Vector K)
  REC ==> Record(R: Matrix K, A: Matrix K, Ainv: Matrix K)
```

```
Exports ==> with
  normalForm: (Matrix K, Automorphism K, K -> K) -> REC
    ++ normalForm(M, sig, der) returns \spad{[R, A, A^{-1}]} such that
    ++ the pseudo-linear operator whose matrix in the basis \spad{y} is
    ++ \spad{M} had matrix \spad{R} in the basis \spad{z = A y}.
    ++ \spad{der} is a \spad{sig}-derivation.
  changeBase: (Matrix K, Matrix K, Automorphism K, K -> K) -> Matrix K
    ++ changeBase(M, A, sig, der): computes the new matrix of a pseudo-linear
    ++ transform given by the matrix M under the change of base A
  companionBlocks: (Matrix K, Vector K) -> List ER
    ++ companionBlocks(m, v) returns \spad{[[C_1, g_1],...,[C_k, g_k]]}
    ++ such that each \spad{C_i} is a companion block and
    ++ \spad{m = diagonal(C_1,...,C_k)}.

Implementation ==> add
  normalForm0: (Matrix K, Automorphism K, Automorphism K, K -> K) -> REC
  mulMatrix: (Integer, Integer, K) -> Matrix K
    -- mulMatrix(N, i, a): under a change of base with the resulting matrix of
    -- size N*N the following operations are performed:
    -- D1: column i will be multiplied by sig(a)
    -- D2: row i will be multiplied by 1/a
    -- D3: addition of der(a)/a to the element at position (i,i)
  addMatrix: (Integer, Integer, Integer, K) -> Matrix K
    -- addMatrix(N, i, k, a): under a change of base with the resulting matrix
    -- of size N*N the following operations are performed:
    -- C1: addition of column i multiplied by sig(a) to column k
    -- C2: addition of row k multiplied by -a to row i
    -- C3: addition of -a*der(a) to the element at position (i,k)
  permutationMatrix: (Integer, Integer, Integer) -> Matrix K
    -- permutationMatrix(N, i, k): under a change of base with the resulting
    -- permutation matrix of size N*N the following operations are performed:
    -- P1: columns i and k will be exchanged
    -- P2: rows i and k will be exchanged
  inv: Matrix K -> Matrix K
    -- inv(M): computes the inverse of a invertable matrix M.

17.69 package PRS PseudoRemainderSequence

The package constructor **PseudoRemainderSequence** provides efficient algorithms by Lionel Ducos (University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

17.69.1 PseudoRemainderSequence (PRS)

++ Author: Manuel Bronstein
++ Date Created: 27 May 1988
++ Date Last Updated: 24 June 1994
++ Description:
++ Integration of pure algebraic functions;
++ This package provides functions for integration, limited integration,
++ extended integration and the risch differential equation for
++ pure algebraic integrands;

PureAlgebraicIntegration(R, F, L): Exports == Implementation where
  R: Join(GcdDomain,RetractableTo Integer,OrderedSet, CharacteristicZero,
          LinearlyExplicitRingOver Integer)
  F: Join(FunctionSpace R, AlgebraicallyClosedField,
          TranscendentalFunctionCategory)
  L: SetCategory

  SY  ==> Symbol
  N   ==> NonNegativeInteger
  K   ==> Kernel F
  P   ==> SparseMultivariatePolynomial(R, K)
  UP  ==> SparseUnivariatePolynomial F
  RF  ==> Fraction UP
  UPUP==> SparseUnivariatePolynomial RF
  IR  ==> IntegrationResult F
  IR2 ==> IntegrationResultFunctions2(curve, F)
  ALG ==> AlgebraicIntegrate(R, F, UP, UPUP, curve)

  U3  ==> Union(Record(mainpart:F, limitedlogs:List LOG), "failed")
  FAIL==> error "failed - cannot handle that integrand"

  Exports ==> with
    palgint   : (F, K, K)    -> IR
      ++ palgint(f, x, y) returns the integral of \spad{f(x,y)dx}
      ++ where y is an algebraic function of x.
    palgextint: (F, K, K, F) -> U2
      ++ palgextint(f, x, y, g) returns functions \spad{[h, c]} such that
      ++ \spad{dh/dx = f(x,y) - c g}, where y is an algebraic function of x;
      ++ returns "failed" if no such functions exist.
    palglimint: (F, K, K, List F) -> U3
```

```
    ++ palglimint(f, x, y, [u1,...,un]) returns functions
    ++ \spad{[h,[[ci, ui]]]} such that the ui's are among \spad{[u1,...,un]}
    ++ and \spad{d(h + sum(ci log(ui)))/dx = f(x,y)} if such functions exist,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x.
  palgRDE   : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
    ++ palgRDE(nfp, f, g, x, y, foo) returns a function \spad{z(x,y)}
    ++ such that \spad{dz/dx + n * df/dx z(x,y) = g(x,y)} if such a z exists,
    ++ "failed" otherwise;
    ++ y is an algebraic function of x;
    ++ \spad{foo(a, b, x)} is a function that solves
    ++ \spad{du/dx + n * da/dx u(x) = u(x)}
    ++ for an unknown \spad{u(x)} not involving y.
    ++ \spad{nfp} is \spad{n * df/dx}.
  if L has LinearOrdinaryDifferentialOperatorCategory F then
    palgLODE: (L, F, K, K, SY) -> REC
      ++ palgLODE(op, g, kx, y, x) returns the solution of \spad{op f = g}.
      ++ y is an algebraic function of x.

18.1 package QALGSET2 QuasiAlgebraicSet2

18.1.1 QuasiAlgebraicSet2 (QALGSET2)

Exports:
radicalSimplify

— package QALGSET2 QuasiAlgebraicSet2 —

```
)abbrev package QALGSET2 QuasiAlgebraicSet2
++ Author:  William Sit
++ Date Created: March 13, 1992
++ Date Last Updated: June 12, 1992
++ Basic Operations:
++ Related Constructors:GroebnerPackage, IdealDecompositionPackage,
++                       PolynomialIdeals
++ See Also: QuasiAlgebraicSet
++ AMS Classifications:
```

```
++ Keywords: Zariski closed sets, quasi-algebraic sets
++ References:William Sit, "An Algorithm for Parametric Linear Systems"
++            J. Sym. Comp., April, 1992
++ Description:
++ \spadtype{QuasiAlgebraicSet2} adds a function \spadfun{radicalSimplify}
++ which uses \spadtype{IdealDecompositionPackage} to simplify
++ the representation of a quasi-algebraic set.  A quasi-algebraic set
++ is the intersection of a Zariski
++ closed set, defined as the common zeros of a given list of
++ polynomials (the defining polynomials for equations), and a principal
++ Zariski open set, defined as the complement of the common
++ zeros of a polynomial f (the defining polynomial for the inequation).
++ Quasi-algebraic sets are implemented in the domain
++ \spadtype{QuasiAlgebraicSet}, where two simplification routines are
++ provided:
++ \spadfun{idealSimplify} and \spadfun{simplify}.
++ The function
++ \spadfun{radicalSimplify} is added
++ for comparison study only.  Because the domain
++ \spadtype{IdealDecompositionPackage} provides facilities for
++ computing with radical ideals, it is necessary to restrict
++ the ground ring to the domain \spadtype{Fraction Integer},
++ and the polynomial ring to be of type
++ \spadtype{DistributedMultivariatePolynomial}.
++ The routine \spadfun{radicalSimplify} uses these to compute groebner
++ basis of radical ideals and
++ is inefficient and restricted when compared to the
++ two in \spadtype{QuasiAlgebraicSet}.

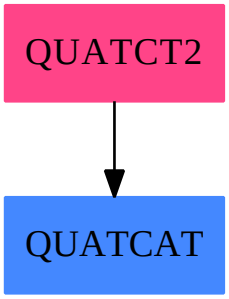
=====================================================================
QuaternionCategoryFunctions2 examples
=====================================================================

The package QuaternionCategoryFunctions2 provides a function map
to convert an expression in Quaternion(R) to an expression in
Quaternion(S) using the function f.

q := quatern(2/11,-8,3/4,1)

         2        3
        -- - 8i + - j + k
        11        4
                                      Type: Quaternion Fraction Integer



f(a:Fraction Integer):Complex Fraction Integer == a::Complex Fraction Integer
   Function declaration f : Fraction Integer -> Complex Fraction
      Integer has been added to workspace.
                                                                  Type: Void

map(f,q)
   Compiling function f with type Fraction Integer -> Complex Fraction
      Integer
```

```
 2        3
-- - 8i + - j + k
11        4
                                  Type: Quaternion Complex Fraction Integer
```

++ Description:
++ Package for the computation of eigenvalues and eigenvectors.
++ This package works for matrices with coefficients which are
++ rational functions over the integers.
++ (see \spadtype{Fraction Polynomial Integer}).
++ The eigenvalues and eigenvectors are expressed in terms of radicals.

RadicalEigenPackage() : C == T
 where
   R     ==> Integer
   P     ==> Polynomial R
   F     ==> Fraction P
   RE    ==> Expression R
   SE    ==> Symbol()
   M     ==> Matrix(F)
   MRE   ==> Matrix(RE)
   ST    ==> SuchThat(SE,P)
   NNI   ==> NonNegativeInteger

   EigenForm    ==> Record(eigval:Union(F,ST),eigmult:NNI,eigvec:List(M))
   RadicalForm  ==> Record(radval:RE,radmult:Integer,radvect:List(MRE))

   C == with
     radicalEigenvectors    :  M     ->  List(RadicalForm)
       ++ radicalEigenvectors(m) computes
       ++ the eigenvalues and the corresponding eigenvectors of the
       ++ matrix m;
       ++ when possible, values are expressed in terms of radicals.

     radicalEigenvector       :  (RE,M)     ->  List(MRE)
       ++ radicalEigenvector(c,m) computes the eigenvector(s) of the
       ++ matrix m corresponding to the eigenvalue c;
       ++ when possible, values are
       ++ expressed in terms of radicals.

     radicalEigenvalues     :  M     ->  List RE
       ++ radicalEigenvalues(m) computes the eigenvalues of the matrix m;
       ++ when possible, the eigenvalues are expressed in terms of radicals.

     eigenMatrix       :    M        ->  Union(MRE,"failed")
       ++ eigenMatrix(m) returns the matrix b
       ++ such that \spad{b*m*(inverse b)} is diagonal,
       ++ or "failed" if no such b exists.

     normalise         :    MRE      ->  MRE
       ++ normalise(v) returns the column
       ++ vector v
```

```
      ++ divided by its euclidean norm;
      ++ when possible, the vector v is expressed in terms of radicals.

    gramschmidt      : List(MRE)   ->  List(MRE)
      ++ gramschmidt(lv) converts the list of column vectors lv into
      ++ a set of orthogonal column vectors
      ++ of euclidean length 1 using the Gram-Schmidt algorithm.

    orthonormalBasis  :    M        ->  List(MRE)
      ++ orthonormalBasis(m)  returns the orthogonal matrix b such that
      ++ \spad{b*m*(inverse b)} is diagonal.
      ++ Error: if m is not a symmetric matrix.

19.8 package RATFACT RationalFactorize

19.8.1 RationalFactorize (RATFACT)

Exports:
factor factorSquareFree

— package RATFACT RationalFactorize —

```
)abbrev package RATFACT RationalFactorize
++ Author: P. Gianni
++ Date created: ??
++ Date last updated: December 1993
++ Keywords: factorization, hensel, rational number
++ Description:
++ Factorization of extended polynomials with rational coefficients.
++ This package implements factorization of extended polynomials
++ whose coefficients are rational numbers. It does this by taking the
++ lcm of the coefficients of the polynomial and creating a polynomial
++ with integer coefficients. The algorithm in
++ \spadtype{GaloisGroupFactorizer} is then
++ used to factor the integer polynomial. The result is normalized
++ with respect to the original lcm of the denominators.

```
=====================================================================
RationalFunctionSum examples
=====================================================================

There are 4 different forms of the sum operator in this domain.
They are variations of the types of the input

   sum(i::Polynomial(Integer),variable(i=1..n))

          2
       6i  - 6i + 1
       ------------
            12

   sum(i::Fraction(Polynomial(Integer)),i::Symbol)

          2
       6i  - 6i + 1
       ------------
            12

   sum(i,i=1..n)

        2
       n  + n
       ------
          2

   sum(i::Fraction(Polynomial(Integer)),i=1..n)

        2
       n  + n
       ------
          2

We can compute the sum form on part at a time to see what happens.
First, we make a SegmentBinding(Polynomial(Integer)):

   s:=i=1..n

        i= 1..n
```

```
We pick out the upper and lower bounds of the segment:

   hiseg:=high(segment(s))

        n

   loseg:=low(segment(s))

        1

We pick out the variable from the segment:

   v:=variable s

        i

We create a polynomial we wish to sum:

   p:=i::Polynomial(Integer)

         i

And we create the sum for that polynomial:

   f:=sum(p,v)

           2
         6i  - 6i + 1
         ------------
              12

The new evaluate it at the upper endpoint:

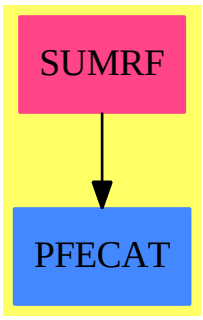
   t1:=eval(f,v,(1+hiseg))

           2
         6n  + 6n + 1
         ------------
              12

And the lower endpoint:

   t2:=eval(f,v,loseg)
```

```
         1
        --
        12
```



And we take the difference of the endpoints:

```
   t1-t2

         2
        n  + n
        ------
           2
```

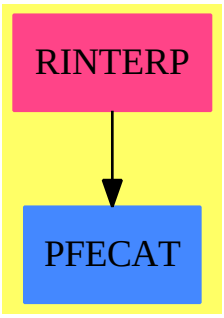
19.18 package RINTERP RationalInterpolation



19.18.1 Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

19.18.2 Questions and Outlook

- Maybe this file should be joined with pinterp.spad, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of pinterp.spad closely.
- There are probably better ways to implement rational interpolation. Maybe http://www.cs.ucsb.edu contains something useful, but I don't know.
- Comments welcome!

19.18.3 RationalInterpolation (RINTERP)

Exports:
interpolate

— **package RINTERP RationalInterpolation** —

```
)abbrev package RINTERP RationalInterpolation
++ Description:
++ This package exports rational interpolation algorithms

RationalInterpolation(xx,F): Exports == Implementation  where
    xx: Symbol
    F: Field
    Exports == with
        interpolate: (List F, List F, NonNegativeInteger,
                                NonNegativeInteger) -> Fraction Polynomial F
```

———-

The implementation sets up a system of linear equations and solves it.

— **package RINTERP RationalInterpolation** —

```
    Implementation == add
        interpolate(xlist, ylist, m, k) ==
```

———-

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine $m + k + 1$ coefficients, where m is the degree of the polynomial in the numerator and k is the degree of the polynomial in the denominator.

In fact, we could also leave – for example – k unspecified and determine it as `k=#xlist-m-1`: I don't know whether this would be better.

— **package RINTERP RationalInterpolation** —

```
#xlist ^= #ylist =>
    error "Different number of points and values."
#xlist ^= m+k+1 =>
    error "wrong number of points"
```

———-

The next step is to set up the matrix. Suppose that our numerator polynomial is $p(x) = a_0 + a_1 x + \ldots + a_m x^m$ and that our denominator polynomial is $q(x) = b_0 + b_1 x + \ldots + b_m x^m$. Then we have the following equations, writing n for $m + k + 1$:

$$\begin{aligned}
p(x_1) - y_1 q(x_1) &= a_0 + a_1 x_1 + \ldots + a_m x_1^m - y_1(b_0 + b_1 x_1 + \ldots + b_k x_1^k) = 0 \\
p(x_2) - y_2 q(x_2) &= a_0 + a_1 x_2 + \ldots + a_m x_2^m - y_2(b_0 + b_1 x_2 + \ldots + b_k x_2^k) = 0 \\
&\vdots \\
p(x_n) - y_n q(x_n) &= a_0 + a_1 x_n + \ldots + a_m x_n^m - y_n(b_0 + b_1 x_n + \ldots + b_k x_n^k) = 0
\end{aligned}$$

This can be written as

$$\begin{bmatrix}
1 & x_1 & \ldots & x_1^m & -y_1 & -y_1 x_1 & \ldots & -y_1 x_1^k \\
1 & x_2 & \ldots & x_2^m & -y_2 & -y_2 x_2 & \ldots & -y_2 x_2^k \\
 & & & \vdots & & & & \\
1 & x_n & \ldots & x_n^m & -y_n & -y_n x_n & \ldots & -y_n x_2^k
\end{bmatrix}
\begin{bmatrix}
a_0 \\ a_1 \\ \vdots \\ a_m \\ b_0 \\ b_1 \\ \vdots \\ b_k
\end{bmatrix} = \mathbf{0}$$

We generate this matrix columnwise:

— **package RINTERP RationalInterpolation** —

```
tempvec: List F := [1 for i in 1..(m+k+1)]

collist: List List F := cons(tempvec,
                             [(tempvec := [tempvec.i * xlist.i _
                                           for i in 1..(m+k+1)]) _
                              for j in 1..max(m,k)])

collist := append([collist.j for j in 1..(m+1)], _
                  [[- collist.j.i * ylist.i for i in 1..(m+k+1)] _
                   for j in 1..(k+1)])
```

———-

Now we can solve the system:

— **package RINTERP RationalInterpolation** —

```
res: List Vector F := nullSpace((transpose matrix collist) _
                                ::Matrix F)
```

———-

Note that it may happen that the system has several solutions. In this case, some of the data points may not be interpolated correctly. However, the solution is often still useful, thus we do not signal an error.

— **package RINTERP RationalInterpolation** —

```
if #res~=1 then output("Warning: unattainable points!" _
                       ::OutputForm)$OutputPackage
```

———-

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:

— **package RINTERP RationalInterpolation** —

```
reslist: List List Polynomial F := _
          [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m], _
          [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
```

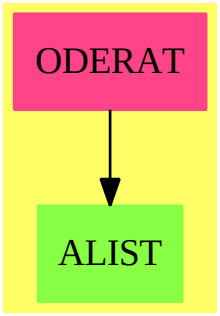
———-

Finally, we generate the rational function:

— **package RINTERP RationalInterpolation** —

```
reduce((_+),reslist.1)/reduce((_+),reslist.2)
```

———-



— **RINTERP.dotabb** —

```
"RINTERP" [color="#FF4488",href="bookvol10.4.pdf#nameddest=RINTERP"]
"PFECAT" [color="#4488FF",href="bookvol10.2.pdf#nameddest=PFECAT"]
"RINTERP" -> "PFECAT"
```

———-

```
Exports ==  with

   rur: (LP,Boolean) -> List RUR
     ++ \spad{rur(lp,univ?)} returns a rational univariate representation
     ++ of \spad{lp}. This assumes that \spad{lp} defines a regular
     ++ triangular \spad{ts} whose associated variety is zero-dimensional
     ++ over \spad{R}. \spad{rur(lp,univ?)} returns a list of items
     ++ \spad{[u,lc]} where \spad{u} is an irreducible univariate polynomial
     ++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
     ++ called the coordinate of \spad{c}, and an extra variable which
     ++ represents any root of \spad{u}. Every root of \spad{u} leads to
     ++ a tuple of values for the coordinates of \spad{lc}. Moreover,
     ++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
     ++ there exists an item \spad{[u,lc]} in \spad{rur(lp,univ?)} and
     ++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
     ++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
     ++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
     ++ will have a constant leading coefficient w.r.t. its coordinate.
     ++ See the example which illustrates the \spadtype{ZeroDimensionalSolvePackage}
     ++ package constructor.
   rur: (LP) -> List RUR
     ++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}

19.23 package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categoris and domains :

The package RealPolynomialUtilitiesPackage whichs receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

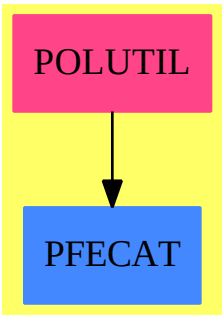
The category RealRootCharacterizationCategory provides abstarct functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category with provides common operations available over real closed fiels. These include finding all the roots of univariate polynomial, taking square roots, ...

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every cretaion function raises a new "real root". This has the effect that when you type something like sqrt(2) + sqrt(2) you have two new variables which happen to be equal. To avoid this name the expression such as in s2 := sqrt(2) ; s2 + s2

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.



LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants

methods usually work best. Betas versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done excatly. They can thus be quite time consuming when depending on several "real roots".

19.28 package RECOP RecurrenceOperator

The package defined in this file provide an operator for the n^{th} term of a recurrence and an operator for the coefficient of x^n in a function specified by a functional equation.

19.28.1 RecurrenceOperator (RECOP)

Exports:

getEq	getOp	evalADE	evalRec
getShiftRec	numberOfValuesNeeded	shiftInfoRec	

— package RECOP RecurrenceOperator —

```
)abbrev package RECOP RecurrenceOperator
++ Author: Martin Rubey
++ Description:
++ This package provides an operator for the n-th term of a recurrence and an
++ operator for the coefficient of x^n in a function specified by a functional
++ equation.

RecurrenceOperator(R, F): Exports == Implementation where
  R: Join(OrderedSet, IntegralDomain, ConvertibleTo InputForm)
  F: Join(FunctionSpace R, AbelianMonoid, RetractableTo Integer, _
          RetractableTo Symbol, PartialDifferentialRing Symbol, _
          CombinatorialOpsCategory)
--RecurrenceOperator(F): Exports == Implementation where
--  F: Join(ExpressionSpace, AbelianMonoid, RetractableTo Integer,
--          RetractableTo Symbol, PartialDifferentialRing Symbol)

  Exports == with
```

```
    evalRec: (BasicOperator, Symbol, F, F, F, List F) -> F
      ++ \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that
      ++ stands for u(n0), where u(n) is given by the equation eq. However, for
      ++ technical reasons the variable n has to be replaced by a dummy
      ++ variable dummy in eq. The argument values specifies the initial values
      ++ of the recurrence u(0), u(1),...
      ++ For the moment we don't allow recursions that contain u inside of
      ++ another operator.

    evalADE: (BasicOperator, Symbol, F, F, F, List F) -> F
      ++ \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that
      ++ stands for the coefficient of x^n in the Taylor expansion of f(x),
      ++ where f(x) is given by the functional equation eq. However, for
      ++ technical reasons the variable x has to be replaced by a dummy
      ++ variable dummy in eq. The argument values specifies the first few
      ++ Taylor coefficients.

    getEq: F -> F
      ++ \spad{getEq f} returns the defining equation, if f represents the
      ++ coefficient of an ADE or a recurrence.

    getOp: F -> BasicOperator
      ++ \spad{getOp f}, if f represents the coefficient of a recurrence or
      ++ ADE, returns the operator representing the solution

  Implementation == add
\getchunk{implementation: RecurrenceOperator}
```

———-

19.28.2 Defining new operators

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the n^{th} term of the corresponding sequence, the other the coefficient of x^n in the Taylor series expansion.

— **implementation: RecurrenceOperator** —

```
oprecur := operator("rootOfRec"::Symbol)$BasicOperator

opADE := operator("rootOfADE"::Symbol)$BasicOperator

setProperty(oprecur, "%dummyVar", 2 pretend None)
setProperty(opADE, "%dummyVar", 2 pretend None)
```

———-

Setting these properties implies that the second and third arguments of oprecur are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (`%defsum` is a good example)

The arguments of the two operators are as follows:

1. eq, i.e. the vanishing expression

   — **implementation: RecurrenceOperator** —

   ```
   eqAsF: List F -> F
   eqAsF l == l.1
   ```

   ———-

2. dummy, a dummy variable to make substitutions possible

   — **implementation: RecurrenceOperator** —

   ```
   dummy: List F -> Symbol
   dummy l == retract(l.2)@Symbol

   dummyAsF: List F -> F
   dummyAsF l == l.2
   ```

   ———-

3. the variable for display

   — **implementation: RecurrenceOperator** —

   ```
   displayVariable: List F -> F
   displayVariable l == l.3
   ```

   ———-

4. operatorName(argument)

— **implementation: RecurrenceOperator** —

```
operatorName: List F -> BasicOperator
operatorName l == operator(kernels(l.4).1)

operatorNameAsF: List F -> F
operatorNameAsF l == l.4

operatorArgument: List F -> F
operatorArgument l == argument(kernels(l.4).1).1
```

———-

Concerning rootOfADE, note that although we have arg as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. values in reversed order.

   - rootOfRec: maybe values should be preceded by the index of the first given value. Currently, the last value is interpreted as $f(0)$.
   - rootOfADE: values are the first few coefficients of the power series expansion in order.

— **implementation: RecurrenceOperator** —

```
initialValues: List F -> List F
initialValues l == rest(l, 4)
```

———-

19.28.3 Recurrences

Extracting some information from the recurrence

We need to find out wether we can determine the next term of the sequence, and how many initial values are necessary.

— **implementation: RecurrenceOperator** —

```
if R has Ring then
  getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol)
              : Union(Integer, "failed") ==
      a := argument f
      if every?(z +-> freeOf?(z, n::F), a) then return 0
```

```
          if #a ~= 1 then error "RECOP: operator should have only one argument"

          p := univariate(a.1, retract(n::F)@Kernel(F))
          if denominator p ~= 1 then return "failed"

          num := numer p

          if degree num = 1 and coefficient(num, 1) = 1

19.28.4 Functional Equations

Determining the number of initial values for ADE's

We use Joris van der Hoeven's instructions for ADE's. Given $Q = p(f, f', \ldots, f^{(r)})$ we first need to differentiate Q with respect to $f^{(i)}$ for $i \in \{0, 1, \ldots, r\}$, plug in the given truncated power series solution and determine the valuation.

— **NOTYET implementation: RecurrenceOperator** —

```
getValuation(op, argsym, eq, maxorder, values): Integer ==
    max: Integer := -1;
    ker: Kernel F
    for i in 0..maxorder repeat
        ker := D(op(argsym), argsym, i)::Kernel F
```

```
            pol := univariate(eq, ker)
            dif := D pol
            ground numer(dif.D(op(argsym), argsym, i))
```

———-

Extracting some information from the functional equation

getOrder returns the maximum derivative of op occurring in f.

— implementation: RecurrenceOperator —

```
    getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
      res: NonNegativeInteger := 0
      g := f
      while is?(g, %diff) repeat
        g := kernels(argument(g).1).1
        res := res+1

      if is?(g, op) then res else 0
```

++ Author: Marc Moreno Maza
++ Date Created: 09/16/1998
++ Date Last Updated: 12/16/1998
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References :
++  [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are proposed:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard
++ methods). This algorithm is valid for nay type
++ of regular set. It does not care about the way a polynomial is
++ added in an regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
++ These operations are realized respectively by the domain \spad{TS}
++ and the packages
```

```
++ \axiomType{QCMPACK}(R,E,V,P,TS) and \axiomType{RSETGCD}(R,E,V,P,TS).
++ The same way it does not care about the way univariate polynomial
++ gcd (with coefficients in the tower of simple extensions associated
++ with a regular set) are computed. The only requirement is that these
++ gcd need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call diectly any operation
++ of this package since they can be accessed by the domain \axiom{TS}.
++ Thus, the operations of this package are not documented.

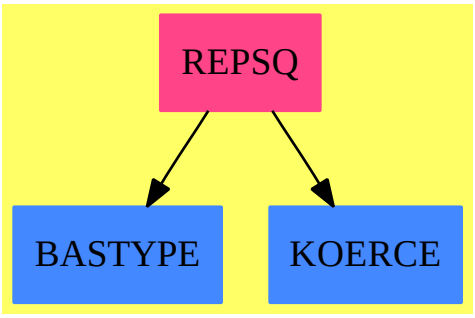
19.35 package REPSQ RepeatedSquaring

This code computes x^n by repeated squaring. It takes advantage of the law of exponents so that if $n = a * b$ then



$$x^n = x^a x^b$$

It also takes advantage of the fact that n has a binary representation so that a one-bit right-shift of a number divides it by 2. Thus we get three cases:

$$\begin{aligned} &n = 1 \rightarrow x^1 \\ &n \text{ odd} \rightarrow \text{repeatedsquare}(x * x, n/2) * x \\ &n \text{ even} \rightarrow \text{repeatedsquare}(x * x, n/2) \end{aligned}$$

Since each recursive call divides n by 2 the algorithm is O(log(n)).

++ Description:
++ RepresentationPackage1 provides functions for representation theory
++ for finite groups and algebras.
++ The package creates permutation representations and uses tensor products
++ and its symmetric and antisymmetric components to create new
++ representations of larger degree from given ones.
++ Note that instead of having parameters from \spadtype{Permutation}
++ this package allows list notation of permutations as well:
++ e.g. \spad{[1,4,3,2]} denotes permutes 2 and 4 and fixes 1 and 3.

++ Description:
++ RepresentationPackage2 provides functions for working with
++ modular representations of finite groups and algebra.
++ The routines in this package are created, using ideas of R. Parker,
++ (the meat-Axe) to get smaller representations from bigger ones,
++ i.e. finding sub- and factormodules, or to show, that such the
++ representations are irreducible.
++ Note that most functions are randomized functions of Las Vegas type
++ i.e. every answer is correct, but with small probability
++ the algorithm fails to get an answer.

  public ==> with

    completeEchelonBasis : V V R  ->  M R
      ++ completeEchelonBasis(lv) completes the basis lv assumed
      ++ to be in echelon form of a subspace of R**n (n the length
```

```
    ++ of all the vectors in lv with unit vectors to a basis of
    ++ R**n. It is assumed that the argument is not an empty
    ++ vector and that it is not the basis of the 0-subspace.
    ++ Note that the rows of the result correspond to the vectors
    ++ of the basis.
  createRandomElement : (L M R, M R) -> M R
    ++ createRandomElement(aG,x) creates a random element of the group
    ++ algebra generated by aG.
  -- randomWord : (L L I, L M)  ->  M R
    --++ You can create your own 'random' matrix with "randomWord(lli, lm)".
    --++ Each li in lli determines a product of matrices, the entries in li
    --++ determine which matrix from lm is chosen. Finally we sum over all
    --++ products. The result "sm" can be used to call split with (e.g.)
    --++ second parameter "first nullSpace sm"
  if R has EuclideanDomain then   -- using rowEchelon
    cyclicSubmodule  : (L M R, V R) ->   V V R
      ++ cyclicSubmodule(lm,v) generates a basis as follows.
      ++ It is assumed that the size n of the vector equals the number
      ++ of rows and columns of the matrices. Then the matrices generate
      ++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
      ++ dimension n. V R is an \spad{A}-module in the natural way.
      ++ cyclicSubmodule(lm,v) generates the R-Basis of Av as
      ++ described in section 6 of R. A. Parker's "The Meat-Axe".
      ++ Note that in contrast to the description in "The Meat-Axe" and to
      ++ standardBasisOfCyclicSubmodule the result is in echelon form.
    standardBasisOfCyclicSubmodule  : (L M R, V R) ->   M R
      ++ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
      ++ It is assumed that the size n of the vector equals the number
      ++ of rows and columns of the matrices.  Then the matrices generate
      ++ a subalgebra, say \spad{A},
      ++ of the algebra of all square matrices of
      ++ dimension n. V R is an \spad{A}-module in the natural way.
      ++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
      ++ non-zero column vectors are the R-Basis of Av achieved
      ++ in the way as described in section 6
      ++ of R. A. Parker's "The Meat-Axe".
      ++ Note that in contrast to cyclicSubmodule, the result is not
      ++ in echelon form.
  if R has Field then  -- only because of inverse in SM
    areEquivalent? : (L M R, L M R, B, I) -> M R
      ++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
      ++ whether the two lists of matrices, all assumed of same
      ++ square shape, can be simultaneously conjugated by a non-singular
      ++ matrix. If these matrices represent the same group generators,
      ++ the representations are equivalent.
      ++ The algorithm tries
      ++ numberOfTries times to create elements in the
      ++ generated algebras in the same fashion. If their ranks differ,
      ++ they are not equivalent. If an
      ++ isomorphism is assumed, then
```

```
  ++ the kernel of an element of the first algebra
  ++ is mapped to the kernel of the corresponding element in the
  ++ second algebra. Now consider the one-dimensional ones.
  ++ If they generate the whole space (e.g. irreducibility !)
  ++ we use standardBasisOfCyclicSubmodule to create the
  ++ only possible transition matrix. The method checks whether the
  ++ matrix conjugates all corresponding matrices from aGi.
  ++ The way to choose the singular matrices is as in meatAxe.
  ++ If the two representations are equivalent, this routine
  ++ returns the transformation matrix TM with
  ++ aG0.i * TM = TM * aG1.i for all i. If the representations
  ++ are not equivalent, a small 0-matrix is returned.
  ++ Note that the case
  ++ with different sets of group generators cannot be handled.
areEquivalent? : (L M R, L M R) -> M R
  ++ areEquivalent?(aG0,aG1) calls areEquivalent?(aG0,aG1,true,25).
  ++ Note that the choice of 25 was rather arbitrary.
areEquivalent? : (L M R, L M R, I) -> M R
  ++ areEquivalent?(aG0,aG1,numberOfTries) calls
  ++ areEquivalent?(aG0,aG1,true,25).
  ++ Note that the choice of 25 was rather arbitrary.
isAbsolutelyIrreducible? : (L M R, I) -> B
  ++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
  ++ Norton's irreducibility test to check for absolute
  ++ irreduciblity, assuming if a one-dimensional kernel is found.
  ++ As no field extension changes create "new" elements
  ++ in a one-dimensional space, the criterium stays true
  ++ for every extension. The method looks for one-dimensionals only
  ++ by creating random elements (no fingerprints) since
  ++ a run of meatAxe would have proved absolute irreducibility
  ++ anyway.
isAbsolutelyIrreducible? : L M R -> B
  ++ isAbsolutelyIrreducible?(aG) calls
  ++ isAbsolutelyIrreducible?(aG,25).
  ++ Note that the choice of 25 was rather arbitrary.
split : (L M R, V R)  ->  L L M R
  ++ split(aG, vector) returns a subalgebra \spad{A} of all
  ++ square matrix of dimension n as a list of list of matrices,
  ++ generated by the list of matrices aG, where n denotes both
  ++ the size of vector as well as the dimension of each of the
  ++ square matrices.
  ++ V R is an A-module in the natural way.
  ++ split(aG, vector) then checks whether the cyclic submodule
  ++ generated by vector is a proper submodule of V R.
  ++ If successful, it returns a two-element list, which contains
  ++ first the list of the representations of the submodule,
  ++ then the list of the representations of the factor module.
  ++ If the vector generates the whole module, a one-element list
  ++ of the old representation is given.
  ++ Note that a later version this should call the other split.
```

```
    split:  (L M R, V V R) -> L L M R
      ++ split(aG,submodule) uses a proper submodule of R**n
      ++ to create the representations of the submodule and of
      ++ the factor module.
  if (R has Finite) and (R has Field) then
    meatAxe  : (L M R, B, I, I)  ->  L L M R
      ++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
      ++ a 2-list of representations as follows.
      ++ All matrices of argument aG are assumed to be square
      ++ and of equal size.
      ++ Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra
      ++ of all square matrices of dimension n. V R is an A-module
      ++ in the usual way.
      ++ meatAxe(aG,numberOfTries, maxTests) creates at most
      ++ numberOfTries random elements of the algebra, tests
      ++ them for singularity. If singular, it tries at most maxTests
      ++ elements of its kernel to generate a proper submodule.
      ++ If successful, a 2-list is returned: first, a list
      ++ containing first the list of the
      ++ representations of the submodule, then a list of the
      ++ representations of the factor module.
      ++ Otherwise, if we know that all the kernel is already
      ++ scanned, Norton's irreducibility test can be used either
      ++ to prove irreducibility or to find the splitting.
      ++ If randomElements is false, the first 6 tries
      ++ use Parker's fingerprints.
    meatAxe : L M R -> L L M R
      ++ meatAxe(aG) calls meatAxe(aG,false,25,7) returns
      ++ a 2-list of representations as follows.
      ++ All matrices of argument \spad{aG} are assumed to be square
      ++ and of
      ++ equal size. Then \spad{aG} generates a subalgebra,
      ++ say \spad{A}, of the algebra
      ++ of all square matrices of dimension n. V R is an A-module
      ++ in the usual way.
      ++ meatAxe(aG) creates at most 25 random elements
      ++ of the algebra, tests
      ++ them for singularity. If singular, it tries at most 7
      ++ elements of its kernel to generate a proper submodule.
      ++ If successful a list which contains first the list of the
      ++ representations of the submodule, then a list of the
      ++ representations of the factor module is returned.
      ++ Otherwise, if we know that all the kernel is already
      ++ scanned, Norton's irreducibility test can be used either
      ++ to prove irreducibility or to find the splitting.
      ++ Notes: the first 6 tries use Parker's fingerprints.
      ++ Also, 7 covers the case of three-dimensional kernels over
      ++ the field with 2 elements.
    meatAxe: (L M R, B) ->  L L M R
      ++ meatAxe(aG, randomElements) calls meatAxe(aG,false,6,7),
```

```
      ++ only using Parker's fingerprints, if randomElemnts is false.
      ++ If it is true, it calls meatAxe(aG,true,25,7),
      ++ only using random elements.
      ++ Note that the choice of 25 was rather arbitrary.
      ++ Also, 7 covers the case of three-dimensional kernels over the field
      ++ with 2 elements.
    meatAxe : (L M R, PI)  ->  L L M R
      ++ meatAxe(aG, numberOfTries) calls
      ++ meatAxe(aG,true,numberOfTries,7).
      ++ Notes: 7 covers the case of three-dimensional
      ++ kernels over the field with 2 elements.
    scanOneDimSubspaces: (L V R, I)  ->  V R
      ++ scanOneDimSubspaces(basis,n) gives a canonical representative
      ++ of the n-th one-dimensional subspace of the vector space
      ++ generated by the elements of basis, all from R**n.
      ++ The coefficients of the representative are of shape
      ++ (0,...,0,1,*,...,*), * in R. If the size of R
      ++ is q, then there are (q**n-1)/(q-1) of them.
      ++ We first reduce n modulo this number, then find the
      ++ largest i such that +/[q**i for i in 0..i-1] <= n.
      ++ Subtracting this sum of powers from n results in an
      ++ i-digit number to basis q. This fills the positions of the
      ++ stars.
      -- would prefer to have (V V R,....   but nullSpace  results
      -- in L V R

19.38 package RESLATC ResolveLatticeCompletion

19.38.1 ResolveLatticeCompletion (RESLATC)

Exports:
coerce

— package RESLATC ResolveLatticeCompletion —

```
)abbrev package RESLATC ResolveLatticeCompletion
++ Author: Stephen M. Watt
++ Date Created: 1986
++ Date Last Updated: May 30, 1991
++ Basic Operations:
++ Related Domains: ErrorFunctions, Exit, Void
++ Also See:
++ AMS Classifications:
++ Keywords: mode, resolve, type lattice
++ Examples:
++ References:
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.

ResolveLatticeCompletion(S: Type): with
        coerce: S -> Void
             ++ coerce(s) throws all information about s away.
             ++ This coercion allows values of any type to appear
             ++ in contexts where they will not be used.
             ++ For example, it allows the resolution of different types in
             ++ the \spad{then} and \spad{else} branches when an \spad{if}
             ++ is in a context where the resulting value is not used.
        coerce: Exit -> S
             ++ coerce(e) is never really evaluated.  This coercion is
             ++ used for formal type correctness when a function will not
             ++ return directly to its caller.
```

```
    == add
        coerce(s: S): Void == void()
        coerce(e: Exit): S ==
            error "Bug: Should not be able to obtain value of type Exit"

++ Authors: G. Hache
++ Date Created: 6 Oct 1994
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ This pacackage finds all the roots of a polynomial. If the constant field is
++ not large enough then it returns the list of found zeros and the degree
++ of the extension need to find the other roots missing. If the return
++ degree is 1 then all the roots have been found. If 0 is return
++ for the extension degree then there are an infinite number of zeros,
++ that is you ask for the zeroes of 0. In the case of infinite field
++ a list of all found zeros is kept and for each other call of a function
++ that finds zeroes, a check is made on that list; this is to keep
```

```
++ a kind of "canonical" representation of the elements.
RootsFindingPackage(K):P==T where
  K:Field

  LIST     ==> List
  INT      ==> Integer
  NNI      ==> NonNegativeInteger
  MFINFACT ==> MultFiniteFactorize
  FFFACTSE ==> FiniteFieldFactorizationWithSizeParseBySideEffect
  SUP      ==> SparseUnivariatePolynomial
  REC      ==> Record(zeros:List(K),extDegree:INT)

  P== with

    distinguishedRootsOf: (SUP(K),K) -> REC
      ++ distinguishedRootsOf returns a record consisting of a list of zeros
      ++ of the input polynomial followed by the smallest extension degree
      ++ needed to find all the zeros. If K has
      ++ \spad{PseudoAlgebraicClosureOfFiniteFieldCategory} or
      ++ \spad{PseudoAlgebraicClosureOfRationalNumberCategory} then
      ++ a root is created for each irreducible factor, and only these
      ++ roots are returns and not their conjugate.

    distinguishedCommonRootsOf: (List SUP(K),K) -> REC
      ++ distinguishedCommonRootsOf returns the common zeros of a list of
      ++ polynomial. It returns a record as in distinguishedRootsOf. If 0
      ++ is returned as extension degree then there are an infinite number
      ++ of common zeros (in this case, the polynomial 0 was given in the
      ++ list of input polynomials).

    foundZeroes: () -> List K
      ++ foundZeroes returns the list of already
      ++ found zeros by the functions
      ++ distinguishedRootsOf  and
      ++ distinguishedCommonRootsOf.

20.8 package SCACHE SortedCache

20.8.1 SortedCache (SCACHE)

Exports:
cache clearCache enterInCache

— **package SCACHE SortedCache** —

```
)abbrev package SCACHE SortedCache
```

```
++ Author: Manuel Bronstein
++ Date Created: 31 Oct 1988
++ Date Last Updated: 14 May 1991
++ Description:
++ A sorted cache of a cachable set S is a dynamic structure that
++ keeps the elements of S sorted and assigns an integer to each
++ element of S once it is in the cache. This way, equality and ordering
++ on S are tested directly on the integers associated with the elements
++ of S, once they have been entered in the cache.

SortedCache(S:CachableSet): Exports == Implementation where
  N    ==> NonNegativeInteger
  DIFF ==> 1024

  Exports ==> with
    clearCache  : () -> Void
      ++ clearCache() empties the cache.
    cache       : () -> List S
      ++ cache() returns the current cache as a list.
    enterInCache: (S, S -> Boolean) -> S
      ++ enterInCache(x, f) enters x in the cache, calling \spad{f(y)} to
      ++ determine whether x is equal to y. It returns x with an integer
      ++ associated with it.
    enterInCache: (S, (S, S) -> Integer) -> S
      ++ enterInCache(x, f) enters x in the cache, calling \spad{f(x, y)} to
      ++ determine whether \spad{x < y (f(x,y) < 0), x = y (f(x,y) = 0)}, or
      ++ \spad{x > y (f(x,y) > 0)}.
      ++ It returns x with an integer associated with it.

  Implementation ==> add

++ References :
++  [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are provided:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard-
++ Moreno methods). This algorithm is valid for nay type
++ of regular set. It does not care about the way a polynomial is
++ added in an regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
++ These operations are realized respectively by the domain \spad{TS}
++ and the packages \spad{QCMPPK(R,E,V,P,TS)} and \spad{RSETGCD(R,E,V,P,TS)}.
++ The same way it does not care about the way univariate polynomial
++ gcds (with coefficients in the tower of simple extensions associated
++ with a regular set) are computed. The only requirement is that these
++ gcds need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call diectly any operation
++ of this package since they can be accessed by the domain \axiomType{TS}.
++ Thus, the operations of this package are not documented.

++ Description:
++ A internal package for computing gcds and resultants of univariate
++ polynomials with coefficients in a tower of simple extensions of a field.
++ There is no need to use directly this package since its main operations are
++ available from \spad{TS}.

SquareFreeRegularTriangularSetGcdPackage(R,E,V,P,TS): Exports == Implementation where

  R : GcdDomain
  E : OrderedAbelianMonoidSup
  V : OrderedSet
  P : RecursivePolynomialCategory(R,E,V)
  TS : RegularTriangularSetCategory(R,E,V,P)

++ This package provides standard arithmetic operations on matrices.
++ The functions in this package store the results of computations
++ in existing matrices, rather than creating new matrices.  This
++ package works only for matrices of type Matrix and uses the
++ internal representation of this type.

StorageEfficientMatrixOperations(R): Exports == Implementation where
  R     : Ring

20.20 package STTAYLOR StreamTaylorSeriesOperations

Problems raising a UTS to a negative integer power.

The code in powern(rn,x) which raises an unnecessary error where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can just take the definition there.

  ++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}.
int          : A -> ST A
  ++ int(r) returns [r,r+1,r+2,...], where r is a ring element.
mapmult      : (ST A,ST A) -> ST A
  ++ mapmult([a0,a1,..],[b0,b1,..])
  ++ returns \spad{[a0*b0,a1*b1,..]}.
deriv        : ST A -> ST A
  ++ deriv(a) returns the derivative of the power series with
  ++ respect to the power series variable. Thus
  ++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv       : (I -> A,ST A)  -> ST A
  ++ gderiv(f,[a0,a1,a2,..]) returns
  ++ \spad{[f(0)*a0,f(1)*a1,f(2)*a2,..]}.
coerce       : A -> ST A
  ++ coerce(r) converts a ring element r to a stream with one element.
eval         : (ST A,A) -> ST A
  ++ eval(a,r) returns a stream of partial sums of the power series
  ++ \spad{a} evaluated at the power series variable equal to r.
compose      : (ST A,ST A) -> ST A
  ++ compose(a,b) composes the power series \spad{a} with
  ++ the power series b.
lagrange     : ST A -> ST A
  ++ lagrange(g) produces the power series for f where f is
  ++ implicitly defined as \spad{f(z) = z*g(f(z))}.
revert       : ST A -> ST A
  ++ revert(a) computes the inverse of a power series \spad{a}
  ++ with respect to composition.
  ++ the series should have constant coefficient 0 and first
  ++ order coefficient 1.
addiag       : ST ST A -> ST A
  ++ addiag(x) performs diagonal addition of a stream of streams. if x =
  ++ \spad{[[a<0,0>,a<0,1>,..],[a<1,0>,a<1,1>,..],[a<2,0>,a<2,1>,..],..]}
  ++ and \spad{addiag(x) = [b<0,b<1>,...], then b<k> = sum(i+j=k,a<i,j>)}.
lambert      : ST A -> ST A
  ++ lambert(st) computes \spad{f(x) + f(x**2) + f(x**3) + ...}
  ++ if st is a stream representing \spad{f(x)}.
  ++ This function is used for computing infinite products.
  ++ If \spad{f(x)} is a power series with constant coefficient 1 then
  ++ \spad{prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.
oddlambert   : ST A -> ST A
  ++ oddlambert(st) computes \spad{f(x) + f(x**3) + f(x**5) + ...}
  ++ if st is a stream representing \spad{f(x)}.
  ++ This function is used for computing infinite products.
  ++ If f(x) is a power series with constant coefficient 1 then
  ++ \spad{prod(f(x**(2*n-1)),n=1..infinity) = exp(oddlambert(log(f(x))))}.
```

```
    evenlambert  : ST A -> ST A
      ++ evenlambert(st) computes \spad{f(x**2) + f(x**4) + f(x**6) + ...}
      ++ if st is a stream representing \spad{f(x)}.
      ++ This function is used for computing infinite products.
      ++ If \spad{f(x)} is a power series with constant coefficient 1, then
      ++ \spad{prod(f(x**(2*n)),n=1..infinity) = exp(evenlambert(log(f(x))))}.
    generalLambert : (ST A,I,I) -> ST A
      ++ generalLambert(f(x),a,d) returns
      ++ \spad{f(x**a) + f(x**(a + d)) + f(x**(a + 2 d)) + ...}.
      ++ \spad{f(x)} should have zero constant
      ++ coefficient and \spad{a} and d should be positive.
    multisect    : (I,I,ST A) -> ST A
      ++ multisect(a,b,st)
      ++ selects the coefficients of \spad{x**((a+b)*n+a)},
      ++ and changes them to \spad{x**n}.
    invmultisect : (I,I,ST A) -> ST A
      ++ invmultisect(a,b,st) substitutes \spad{x**((a+b)*n)} for \spad{x**n}
      ++ and multiplies by \spad{x**b}.
    if A has Algebra RN then
      integrate  : (A,ST A) -> ST A
        ++ integrate(r,a) returns the integral of the power series \spad{a}
        ++ with respect to the power series variableintegration where
        ++ r denotes the constant of integration. Thus
        ++ \spad{integrate(a,[a0,a1,a2,...]) = [a,a0,a1/2,a2/3,...]}.
      lazyIntegrate  : (A,() -> ST A) -> ST A
        ++ lazyIntegrate(r,f) is a local function
        ++ used for fixed point computations.
      nlde       : ST ST A -> ST A
        ++ nlde(u) solves a
        ++ first order non-linear differential equation described by u of the
        ++ form \spad{[[b<0,0>,b<0,1>,...],[b<1,0>,b<1,1>,.],...]}.
        ++ the differential equation has the form
        ++ \spad{y'=sum(i=0 to infinity,j=0 to infinity,b<i,j>*(x**i)*(y**j))}.
      powern : (RN,ST A) -> ST A
        ++ powern(r,f) raises power series f to the power r.
    if A has Field then
      mapdiv     : (ST A,ST A) -> ST A
        ++ mapdiv([a0,a1,..],[b0,b1,..]) returns
        ++ \spad{[a0/b0,a1/b1,..]}.
      lazyGintegrate : (I -> A,A,() -> ST A) -> ST A
        ++ lazyGintegrate(f,r,g) is used for fixed point computations.
      power      : (A,ST A) -> ST A
        ++ power(a,f) returns the power series f raised to the power \spad{a}.

      ++ cot(st) computes cotangent of a power series st.
    sec     : ST -> ST
      ++ sec(st) computes secant of a power series st.
    csc     : ST -> ST
      ++ csc(st) computes cosecant of a power series st.
    asin    : ST -> ST
      ++ asin(st) computes arcsine of a power series st.
    acos    : ST -> ST
      ++ acos(st) computes arccosine of a power series st.
    atan    : ST -> ST
      ++ atan(st) computes arctangent of a power series st.
    acot    : ST -> ST
      ++ acot(st) computes arccotangent of a power series st.
    asec    : ST -> ST
      ++ asec(st) computes arcsecant of a power series st.
    acsc    : ST -> ST
      ++ acsc(st) computes arccosecant of a power series st.

--% HyperbloicTrigonometricFunctionCategory
    sinhcosh: ST -> Record(sinh:ST, cosh:ST)
      ++ sinhcosh(st) returns a record containing
      ++ the hyperbolic sine and cosine
      ++ of a power series st.
    sinh    : ST -> ST
      ++ sinh(st) computes the hyperbolic sine of a power series st.
    cosh    : ST -> ST
      ++ cosh(st) computes the hyperbolic cosine of a power series st.
    tanh    : ST -> ST
```

```
      ++ tanh(st) computes the hyperbolic tangent of a power series st.
    coth    : ST -> ST
      ++ coth(st) computes the hyperbolic cotangent of a power series st.
    sech    : ST -> ST
      ++ sech(st) computes the hyperbolic secant of a power series st.
    csch    : ST -> ST
      ++ csch(st) computes the hyperbolic cosecant of a power series st.
    asinh   : ST -> ST
      ++ asinh(st) computes the inverse hyperbolic sine of a power series st.
    acosh   : ST -> ST
      ++ acosh(st) computes the inverse hyperbolic cosine
      ++ of a power series st.
    atanh   : ST -> ST
      ++ atanh(st) computes the inverse hyperbolic tangent
      ++ of a power series st.
    acoth   : ST -> ST
      ++ acoth(st) computes the inverse hyperbolic
      ++ cotangent of a power series st.
    asech   : ST -> ST
      ++ asech(st) computes the inverse hyperbolic secant of a
      ++ power series st.
    acsch   : ST -> ST
      ++ acsch(st) computes the inverse hyperbolic
      ++ cosecant of a power series st.

```
)abbrev package SCPKG StructuralConstantsPackage
++ Authors: J. Grabmeier
++ Date Created: 02 April 1992
++ Date Last Updated: 14 April 1992
++ Basic Operations:
++ Related Constructors: AlgebraPackage, AlgebraGivenByStructuralConstants
++ Also See:
++ AMS Classifications:
++ Keywords: structural constants
++ Reference:
++ Description:
++ StructuralConstantsPackage provides functions creating
++ structural constants from a multiplication tables or a basis
++ of a matrix algebra and other useful functions in this context.

StructuralConstantsPackage(R:Field): public == private where

  L  ==> List
  S  ==> Symbol
  FRAC ==> Fraction
  POLY ==> Polynomial
  V  ==> Vector
  M  ==> Matrix
  REC  ==> Record(particular: Union(V R,"failed"),basis: List V R)
  LSMP ==> LinearSystemMatrixPackage(R,V R,V R, M R)

  public ==>  with
      -- what we really want to have here is a matrix over
      -- linear polynomials in the list of symbols, having arbitrary
      -- coefficients from a ring extension of R, e.g. FRAC POLY R.
      structuralConstants : (L S, M FRAC POLY R) -> V M FRAC POLY R
        ++ structuralConstants(ls,mt) determines the structural constants
        ++ of an algebra with generators ls and multiplication table mt, the
        ++ entries of which must be given as linear polynomials in the
        ++ indeterminates given by ls. The result is in particular useful
        ++  as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
        ++  and \spadtype{GenericNonAssociativeAlgebra}.
      structuralConstants : (L S, M POLY R) -> V M POLY R
        ++ structuralConstants(ls,mt) determines the structural constants
        ++ of an algebra with generators ls and multiplication table mt, the
        ++ entries of which must be given as linear polynomials in the
        ++ indeterminates given by ls. The result is in particular useful
        ++  as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
        ++  and \spadtype{GenericNonAssociativeAlgebra}.
      structuralConstants: L M R -> V M R
        ++ structuralConstants(basis)  takes the basis of a matrix
        ++ algebra, e.g. the result of \spadfun{basisOfCentroid} and calculates
        ++ the structural constants.
        ++ Note, that the it is not checked, whether basis really is a
        ++ basis of a matrix algebra.
```

```
      coordinates: (M R, L M R) -> V R
        ++ coordinates(a,[v1,...,vn]) returns the coordinates of \spad{a}
        ++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

20.26 package SUBRESP SubResultantPackage

20.26.1 SubResultantPackage (SUBRESP)

Exports:
primitivePart subresultantVector

— package SUBRESP SubResultantPackage —

```
)abbrev package SUBRESP SubResultantPackage
++ Author: Barry Trager, Renaud Rioboo
++ Date Created: 1987
++ Date Last Updated: August 2000
++ Description:
++ This package computes the subresultants of two polynomials which is needed
++ for the 'Lazard Rioboo' enhancement to Tragers integrations formula
++ For efficiency reasons this has been rewritten to call Lionel Ducos
++ package which is currently the best one.

SubResultantPackage(R, UP): Exports == Implementation where
  R : IntegralDomain
  UP: UnivariatePolynomialCategory R

  Z   ==> Integer
  N   ==> NonNegativeInteger

  Exports ==> with
    subresultantVector: (UP, UP) -> PrimitiveArray UP
      ++ subresultantVector(p, q) returns \spad{[p0,...,pn]}
      ++ where pi is the i-th subresultant of p and q.
      ++ In particular, \spad{p0 = resultant(p, q)}.
    if R has EuclideanDomain then
      primitivePart     : (UP,  R) -> UP
        ++ primitivePart(p, q) reduces the coefficient of p
        ++ modulo q, takes the primitive part of the result,
        ++ and ensures that the leading coefficient of that
```

```
       ++ result is monic.

++ Description:
++ Symbolic solver for systems of rational functions with coefficients
++ in an integral domain R.
++ The systems are solved in the field of rational functions over R.
++ Solutions are exact of the form variable = value when the value is
++ a member of the coefficient domain R. Otherwise the solutions
++ are implicitly expressed as roots of univariate polynomial equations over R.
++ Care is taken to guarantee that the denominators of the input
++ equations do not vanish on the solution sets.
++ The arguments to solve can either be given as equations or
++ as rational functions interpreted as equal
++ to zero. The user can specify an explicit list of symbols to
++ be solved for, treating all other symbols appearing as parameters
++ or omit the list of symbols in which case the system tries to
++ solve with respect to all symbols appearing in the input.
```

--    coerce : M I -> Tableau(I)
--      ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
--      ++ the domain Tableau(I).

    coleman : (L I, L I, L I) -> M I
      ++ coleman(alpha,beta,pi):
      ++ there is a bijection from the set of matrices having nonnegative
      ++ entries and row sums alpha, column sums beta
      ++ to the set of Salpha - Sbeta double cosets of the
      ++ symmetric group Sn. (Salpha is the Young subgroup
      ++ corresponding to the improper partition alpha).
      ++ For a representing element pi of such a double coset,
      ++ coleman(alpha,beta,pi) generates the Coleman-matrix
      ++ corresponding to alpha, beta, pi.
      ++ Note that The permutation pi of {1,2,...,n} has to be given
      ++ in list form.
      ++ Note that the inverse of this map is inverseColeman
      ++ (if pi is the lexicographical smallest permutation
      ++ in the coset). For details see James/Kerber.
    inverseColeman : (L I, L I, M I) -> L I
      ++ inverseColeman(alpha,beta,C):
      ++ there is a bijection from the set of matrices having nonnegative
      ++ entries and row sums alpha, column sums beta
      ++ to the set of Salpha - Sbeta double cosets of the
      ++ symmetric group Sn. (Salpha is the Young subgroup
      ++ corresponding to the improper partition alpha).
      ++ For such a matrix C, inverseColeman(alpha,beta,C)
      ++ calculates the lexicographical smallest pi in the
      ++ corresponding double coset.
      ++ Note that the resulting permutation pi of {1,2,...,n}
      ++ is given in list form.
      ++ Notes: the inverse of this map is coleman.
      ++ For details, see James/Kerber.
    listYoungTableaus : (L I) -> L M I
      ++ listYoungTableaus(lambda) where lambda is a proper partition
      ++ generates the list of all standard tableaus of shape lambda
      ++ by means of lattice permutations. The numbers of the lattice
      ++ permutation are interpreted as column labels. Hence the
      ++ contents of these lattice permutations are the conjugate of
      ++ lambda.
      ++ Notes: the functions nextLatticePermutation and
      ++ makeYoungTableau are used.
      ++ The entries are from 0,...,n-1.
    makeYoungTableau : (L I,L I) -> M I
      ++ makeYoungTableau(lambda,gitter) computes for a given lattice
      ++ permutation gitter and for an improper partition lambda
      ++ the corresponding standard tableau of shape lambda.
      ++ Notes: see listYoungTableaus.
      ++ The entries are from 0,...,n-1.
    nextColeman : (L I, L I, M I) -> M I
```

```
  ++ nextColeman(alpha,beta,C) generates the next Coleman matrix
  ++ of column sums alpha and row sums beta according
  ++ to the lexicographical order from bottom-to-top.
  ++ The first Coleman matrix is achieved by C=new(1,1,0).
  ++ Also, new(1,1,0) indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
  ++ nextLatticePermutation(lambda,lattP,constructNotFirst) generates
  ++ the lattice permutation according to the proper partition
  ++ lambda succeeding the lattice permutation lattP in
  ++ lexicographical order as long as constructNotFirst is true.
  ++ If constructNotFirst is false, the first lattice permutation
  ++ is returned.
  ++ The result nil indicates that lattP has no successor.
nextPartition : (V I, V I, I) -> V I
  ++ nextPartition(gamma,part,number) generates the partition of
  ++ number which follows part according to the right-to-left
  ++ lexicographical order. The partition has the property that
  ++ its components do not exceed the corresponding components of
  ++ gamma. The first partition is achieved by part=[].
  ++ Also, [] indicates that part is the last partition.
nextPartition : (L I, V I, I) -> V I
  ++ nextPartition(gamma,part,number) generates the partition of
  ++ number which follows part according to the right-to-left
  ++ lexicographical order. The partition has the property that
  ++ its components do not exceed the corresponding components of
  ++ gamma. the first partition is achieved by part=[].
  ++ Also, [] indicates that part is the last partition.
numberOfImproperPartitions: (I,I) -> I
  ++ numberOfImproperPartitions(n,m) computes the number of partitions
  ++ of the nonnegative integer n in m nonnegative parts with regarding
  ++ the order (improper partitions).
  ++ Example: numberOfImproperPartitions (3,3) is 10,
  ++ since [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
  ++ [1,2,0], [2,0,1], [2,1,0], [3,0,0] are the possibilities.
  ++ Note that this operation has a recursive implementation.
subSet : (I,I,I) -> L I
  ++ subSet(n,m,k) calculates the k-th m-subset of the set
  ++ 0,1,...,(n-1) in the lexicographic order considered as
  ++ a decreasing map from 0,...,(m-1) into 0,...,(n-1).
  ++ See S.G. Williamson: Theorem 1.60.
  ++ Error: if not (0 <= m <= n and 0 < = k < (n choose m)).
unrankImproperPartitions0 : (I,I,I) -> L I
  ++ unrankImproperPartitions0(n,m,k) computes the k-th improper
  ++ partition of nonnegative n in m nonnegative parts in reverse
  ++ lexicographical order.
  ++ Example: [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
  ++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0].
  ++ Error: if k is negative or too big.
  ++ Note that counting of subtrees is done by
  ++ numberOfImproperPartitions
```

```
  unrankImproperPartitions1: (I,I,I) -> L I
    ++ unrankImproperPartitions1(n,m,k) computes the k-th improper
    ++ partition of nonnegative n in at most m nonnegative parts
    ++ ordered as follows: first, in reverse
    ++ lexicographically according to their non-zero parts, then
    ++ according to their positions (i.e. lexicographical order
    ++ using subSet: [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
    ++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1].
    ++ Note that counting of subtrees is done by
    ++ numberOfImproperPartitionsInternal.

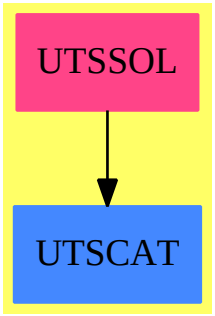
21.4 package UTSSOL TaylorSolve

UTSSOL is a facility to compute the first few coefficients of a Taylor series given only implicitely by a function f that vanishes when applied to the Taylor series.

It uses the method of undetermined coefficients.

```
  Could I either
  \begin{itemize}
  \item take a function UTSCAT F $->$ UTSCAT F and still be able to compute
    with undetermined coefficients, or
```

```
\item take a function F $->$ F, and do likewise?
\end{itemize}



Let's see.

Try to compute the equation without resorting to power series. I.e., %
c: SUP SUP F, and f: SUP SUP F $->$ SUP SUP F. Won't this make the
computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately, SUP F does not have TRANFUN -- well, it can't, of
course. However, I'd like to be able to compute %
sin(1+monomial(1,1)$UFPS SUP EXPR INT).
```

21.4.1 TaylorSolve (UTSSOL)

Exports:
seriesSolve

— package UTSSOL TaylorSolve —

```
)abbrev package UTSSOL TaylorSolve
++ Description:
++ This package has no description

TaylorSolve(F, UTSF, UTSSUPF): Exports == Implementation where
    F: Field
    SUP  ==> SparseUnivariatePolynomialExpressions
    UTSF: UnivariateTaylorSeriesCategory F
    UTSSUPF: UnivariateTaylorSeriesCategory SUP F
    NNI  ==> NonNegativeInteger

    Exports == with
        seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF
```

```
    Implementation == add
\getchunk{implementation: UTSSOL TaylorSolve}
```

———-

— **implementation: UTSSOL TaylorSolve** —

```
        seriesSolve(f, l) ==
            c1 :=
             map((x:F):SUP F +-> x::(SUP F), l)
                  $ListFunctions2(F, SUP F)::(Stream SUP F)
            coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI)))
--            coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))
```

———-

coeffs is the stream of the already computed coefficients of the solution, plus one which is so far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with the first coefficient that has possibly not yet been computed.

```
  The mathematics is not quite worked out. If coeffs is initialized as
  stream with all coefficients set to the \emph{same} transcendental value,
  and not enough initial values are given, then the missing ones are
  implicitely assumed to be all identical. It may well happen that a solution
  is produced, although it is not uniquely determined\dots
```

— **implementation: UTSSOL TaylorSolve** —

```
            st: List Stream SUP F := [coeffs, coeffs]
```

———-

Consider an arbitrary equation $f\big(x, y(x)\big) = 0$. When setting $x = 0$, we obtain $f\big(0, y(0)\big) = 0$. It is not necessarily the case that this determines $y(0)$ uniquely, so we need one initial value that satisfies this equation.

```
  seriesSolve should check that the given initial values satisfy $f\big(0, y(0),
  y'(0),...\big) = 0$.
```

Now consider the derivatives of f, where we write y instead of $y(x)$ for better readability:

$$\frac{d}{dx} f(x, y) = f_1(x, y) + f_2(x, y)y'$$

and

```
\frac{d^2}{dx^2}f(x, y)&=f_{1,1}(x, y)\\
                       &+f_{1,2}(x, y)y^\prime\\
                       &+f_{2,1}(x, y)y^\prime\\
                       &+f_{2,2}(x, y)(y^\prime)^2\\
                       &+f_2(x, y)y^{\prime\prime}.
```

In general, $\frac{d^2}{dx^2}f(x,y)$ depends only linearly on y''.

```
This points to another possibility: Since we know that we only need to solve
linear equations, we could compute two values and then use interpolation.
This might be a bit slower, but more importantly: can we still check that we
have enough initial values? Furthermore, we then really need that $f$ is
analytic, i.e., operators are not necessarily allowed anymore. However, it
seems that composition is allowed.
```

— **implementation: UTSSOL TaylorSolve** —

```
next: () -> F :=
    nr := st.1
    res: F

    if ground?(coeff: SUP F := nr.1)$(SUP F)
```

———-

If the next element was already calculated, we can simply return it:

— **implementation: UTSSOL TaylorSolve** —

```
    then
        res := ground coeff
        st.1 := rest nr
    else
```

———-

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

— **implementation: UTSSOL TaylorSolve** —

```
        ns := st.2
        eqs: Stream SUP F := coefficients f series ns
        while zero? first eqs repeat eqs := rest eqs
        eq: SUP F := first eqs
        if degree eq > 1 then
```

```
                        if monomial? eq then res := 0
                        else
                            output(hconcat("The equation is: ", eq::OutputForm))
                                  $OutputPackage
                            error "seriesSolve: equation for coefficient not linear"
                    else res := (-coefficient(eq, 0$NNI)$(SUP F)
                                 /coefficient(eq, 1$NNI)$(SUP F))

                    nr.1 := res::SUP F
--                    concat!(st.2, monomial(1$F,1$NNI))
                    st.1 := rest nr

                res

            series generate next

    recolor: ((SF,SF) -> Pt,(SF,SF,SF) -> SF) -> ((SF,SF) -> Pt)
      ++ recolor(), uninteresting to top level user; exported in order to
      ++ compile package.

  Implementation ==> add
```

———-

I have had to work my way around the following bug in the compiler: When a local variable is given a mapping as a value, e.g.

```
   foo : SF -> SF := makeFloatFunction(f,t),
```

the compiler cannot distinguish that local variable from a local function defined elsewhere in the package. Thus, when 'foo' is passed to a function, e.g.

```
  bird := fcn(foo),
```

foo will often be compiled as DRAW;foo rather than foo. This, of course, causes a run-time error.

To avoid this problem, local variables are not given mappings as values, but rather (singleton) lists of mappings. The first element of the list can always be extracted and everything goes through as before. There is no major loss in efficiency, as the computation of points will always dominate the computation time.
- cjw, 22 June MCMXC

———-

The function `myTrap1` is a local function for used in creating maps SF -¿ Point SF (two dimensional). The range of this function is SingleFloat. As originally coded it would return `$NaNvalue$Lisp` which is outside the range. Since this function is only used internallly by the draw package we handle the "failed" case by returning zero. We handle the out-of-range case by returning the maximum or minimum SingleFloat value.

———-

The function `myTrap2` is a local function for used in creating maps SF -¿ Point SF (three dimensional). The range of this function is SingleFloat. As originally coded it would return `$NaNvalue$Lisp` which is outside the range. Since this function is only used internallly by the draw package we handle the "failed" case by returning zero. We handle the out-of-range case by returning the maximum or minimum SingleFloat value.

FPR     ==> Fraction Polynomial R

Exports ==> with
  expand     : F -> F
    ++ expand(f) performs the following expansions on f:\begin{items}
    ++ \item 1. logs of products are expanded into sums of logs,
    ++ \item 2. trigonometric and hyperbolic trigonometric functions
    ++ of sums are expanded into sums of products of trigonometric
    ++ and hyperbolic trigonometric functions.
    ++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
    ++ \spad{a**c * b**(-c)}.
    ++ \end{items}
  simplify   : F -> F
    ++ simplify(f) performs the following simplifications on f:\begin{items}
    ++ \item 1. rewrites trigs and hyperbolic trigs in terms
    ++ of \spad{sin} ,\spad{cos}, \spad{sinh}, \spad{cosh}.
    ++ \item 2. rewrites \spad{sin**2} and \spad{sinh**2} in terms
    ++ of \spad{cos} and \spad{cosh},
    ++ \item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
    ++ \item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
    ++ power of a single radical of \spad{a}.
    ++ \end{items}
  htrigs     : F -> F
    ++ htrigs(f) converts all the exponentials in f into
    ++ hyperbolic sines and cosines.
  simplifyExp: F -> F
    ++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
    ++ appearing in f into \spad{exp(a+b)}.
  simplifyLog : F -> F
    ++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
    ++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
    ++ and every \spad{n*log(a)} into \spad{log(a^n)}.
  expandPower: F -> F
    ++ expandPower(f) converts every power \spad{(a/b)**c} appearing
    ++ in f into \spad{a**c * b**(-c)}.
  expandLog  : F -> F
    ++ expandLog(f) converts every \spad{log(a/b)} appearing in f into
    ++ \spad{log(a) - log(b)}, and every \spad{log(a*b)} into
    ++ \spad{log(a) + log(b)}..
  cos2sec    : F -> F
    ++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
    ++ \spad{1/sec(u)}.
  cosh2sech  : F -> F
    ++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
    ++ \spad{1/sech(u)}.
  cot2trig   : F -> F
    ++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
    ++ \spad{cos(u)/sin(u)}.
```

```
coth2trigh : F -> F
  ++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
  ++ \spad{cosh(u)/sinh(u)}.
csc2sin    : F -> F
  ++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
  ++ \spad{1/sin(u)}.
csch2sinh  : F -> F
  ++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
  ++ \spad{1/sinh(u)}.
sec2cos    : F -> F
  ++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
  ++ \spad{1/cos(u)}.
sech2cosh  : F -> F
  ++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
  ++ \spad{1/cosh(u)}.
sin2csc    : F -> F
  ++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
  ++ \spad{1/csc(u)}.
sinh2csch  : F -> F
  ++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
  ++ \spad{1/csch(u)}.
tan2trig   : F -> F
  ++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
  ++ \spad{sin(u)/cos(u)}.
tanh2trigh : F -> F
  ++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
  ++ \spad{sinh(u)/cosh(u)}.
tan2cot    : F -> F
  ++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
  ++ \spad{1/cot(u)}.
tanh2coth  : F -> F
  ++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
  ++ \spad{1/coth(u)}.
cot2tan    : F -> F
  ++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
  ++ \spad{1/tan(u)}.
coth2tanh  : F -> F
  ++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
  ++ \spad{1/tanh(u)}.
removeCosSq: F -> F
  ++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into
  ++ \spad{1 - sin(x)**2}, and also reduces higher
  ++ powers of \spad{cos(u)} with that formula.
removeSinSq: F -> F
  ++ removeSinSq(f) converts every \spad{sin(u)**2} appearing in f into
  ++ \spad{1 - cos(x)**2}, and also reduces higher powers of
  ++ \spad{sin(u)} with that formula.
removeCoshSq:F -> F
  ++ removeCoshSq(f) converts every \spad{cosh(u)**2} appearing in f into
  ++ \spad{1 - sinh(x)**2}, and also reduces higher powers of
```

```
    ++ \spad{cosh(u)} with that formula.
  removeSinhSq:F -> F
    ++ removeSinhSq(f) converts every \spad{sinh(u)**2} appearing in f into
    ++ \spad{1 - cosh(x)**2}, and also reduces higher powers
    ++ of \spad{sinh(u)} with that formula.
  if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R))
   and F has ConvertibleTo(Pattern(R)) and F has PatternMatchable R then
    expandTrigProducts : F -> F
      ++ expandTrigProducts(e) replaces \axiom{sin(x)*sin(y)} by
      ++ \spad{(cos(x-y)-cos(x+y))/2}, \axiom{cos(x)*cos(y)} by
      ++ \spad{(cos(x-y)+cos(x+y))/2}, and \axiom{sin(x)*cos(y)} by
      ++ \spad{(sin(x-y)+sin(x+y))/2}.  Note that this operation uses
      ++ the pattern matcher and so is relatively expensive.  To avoid
      ++ getting into an infinite loop the transformations are applied
      ++ at most ten times.

21.18.1 TransSolvePackage (SOLVETRA)

Exports:
solve

— package SOLVETRA TransSolvePackage —

```
)abbrev package SOLVETRA TransSolvePackage
++ Author: W. Wiwianka, Martin Rubey
++ Date Created: Summer 1991
++ Change History: 9/91
++ Basic Operations: solve
++ Related Constructors: RadicalSolvePackage, FloatingRealPackage
++ Keywords:
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and nthRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression  \spad{sin(x)*cos(x)-2}  will be transformed to
++ \spad{-2 tan(x/2)**4 -2 tan(x/2)**3 -4 tan(x/2)**2 +2 tan(x/2) -2}
++ by  using the function  normalize  and then to
++ \spad{-2 tan(x)**2 + tan(x) -2}
++ with help of subsTan. This function tries to express the given function
++ in terms of \spad{tan(x/2)}  to express in terms of \spad{tan(x)} .
++ Other examples are the expressions    \spad{sqrt(x+1)+sqrt(x+7)+1}   or
++ \spad{sqrt(sin(x))+1} .

++ Author: Victor Miller
++ Date Created:
++ Date Last Updated: 24 Jul 1990
++ Keywords:
++ Examples:
++ References:
++ Description:
++ This package provides functions that compute "fraction-free"
++ inverses of upper and lower triangular matrices over a integral
++ domain.  By "fraction-free inverses" we mean the following:
++ given a matrix B with entries in R and an element d of R such that
++ d * inv(B) also has entries in R, we return d * inv(B).  Thus,
++ it is not necessary to pass to the quotient field in any of our
```

```
++ computations.

TriangularMatrixOperations(R,Row,Col,M): Exports == Implementation where

  Pt  ==> Point SF

  Exports ==> with
    point: (SF,SF,SF,SF) -> Pt
      ++ point(x1,x2,x3,c) creates and returns a point from the three
      ++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
      ++ a fourth coordinate, c, which is generally used to specify the
      ++ color of the point.
    "*" : (SF,Pt) -> Pt
      ++ s * p returns a point whose coordinates are the scalar multiple
      ++ of the point p by the scalar s, preserving the color, or fourth
      ++ coordinate, of p.
    "+" : (Pt,Pt) -> Pt
      ++ p + q computes and returns a point whose coordinates are the sums
```

```
    ++ of the coordinates of the two points \spad{p} and \spad{q}, using
    ++ the color, or fourth coordinate, of the first point \spad{p}
    ++ as the color also of the point \spad{q}.
  "-" : (Pt,Pt) -> Pt
    ++ p - q computes and returns a point whose coordinates are the
    ++ differences of the coordinates of two points \spad{p} and \spad{q},
    ++ using the color, or fourth coordinate, of the first point \spad{p}
    ++ as the color also of the point \spad{q}.
  dot : (Pt,Pt) -> SF
    ++ dot(p,q) computes the dot product of the two points \spad{p}
    ++ and \spad{q} using only the first three coordinates, and returns
    ++ the resulting \spadtype{DoubleFloat}.
  cross : (Pt,Pt) -> Pt
    ++ cross(p,q) computes the cross product of the two points \spad{p}
    ++ and \spad{q} using only the first three coordinates, and keeping
    ++ the color of the first point p.  The result is returned as a point.
  unitVector: Pt -> Pt
    ++ unitVector(p) creates the unit vector of the point p and returns
    ++ the result as a point.  Note that \spad{unitVector(p) = p/|p|}.
  cosSinInfo: I -> L L SF
    ++ cosSinInfo(n) returns the list of lists of values for n, in the form
    ++ \spad{[[cos(n-1) a,sin(n-1) a],...,[cos 2 a,sin 2 a],[cos a,sin a]]}
    ++ where \spad{a = 2 pi/n}.  Note that n should be greater than 2.
  loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
    ++ loopPoints(p,n,b,r,lls) creates and returns a list of points
    ++ which form the loop with radius r, around the center point
    ++ indicated by the point p, with the principal normal vector of
    ++ the space curve at point p given by the point(vector) n, and the
    ++ binormal vector given by the point(vector) b, and a list of lists,
    ++ lls, which is the \spadfun{cosSinInfo} of the number of points
    ++ defining the loop.

```

```
      ++ clip(p) performs two-dimensional clipping on a plot, p, from
      ++ the domain \spadtype{Plot} for the graph of one variable,
      ++ \spad{y = f(x)}; the default parameters \spad{1/4} for the fraction
      ++ and \spad{5/1} for the scale are used in the \spadfun{clip} function.
    clip: (PLOT,RN,RN) -> CLIPPED
      ++ clip(p,frac,sc) performs two-dimensional clipping on a plot, p,
      ++ from the domain \spadtype{Plot} for the graph of one variable
      ++ \spad{y = f(x)}; the fraction parameter is specified by \spad{frac}
      ++ and the scale parameter is specified by \spad{sc} for use in the
      ++ \spadfun{clip} function.
    clipParametric: PLOT -> CLIPPED
      ++ clipParametric(p) performs two-dimensional clipping on a plot,
      ++ p, from the domain \spadtype{Plot} for the parametric curve
      ++ \spad{x = f(t)}, \spad{y = g(t)}; the default parameters \spad{1/2}
      ++ for the fraction and \spad{5/1} for the scale are used in the
      ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
      ++ function.
    clipParametric: (PLOT,RN,RN) -> CLIPPED
      ++ clipParametric(p,frac,sc) performs two-dimensional clipping on a
      ++ plot, p, from the domain \spadtype{Plot} for the parametric curve
      ++ \spad{x = f(t)}, \spad{y = g(t)}; the fraction parameter is
      ++ specified by \spad{frac} and the scale parameter is specified
      ++ by \spad{sc} for use in the \fakeAxiomFun{iClipParametric} subroutine,
      ++ which is called by this function.
    clipWithRanges: (L L Pt,SF,SF,SF,SF) -> CLIPPED
      ++ clipWithRanges(pointLists,xMin,xMax,yMin,yMax) performs clipping
      ++ on a list of lists of points, \spad{pointLists}.  Clipping is
      ++ done within the specified ranges of \spad{xMin}, \spad{xMax} and
      ++ \spad{yMin}, \spad{yMax}.  This function is used internally by
      ++ the \fakeAxiomFun{iClipParametric} subroutine in this package.
    clip: L Pt -> CLIPPED
      ++ clip(l) performs two-dimensional clipping on a curve l, which is
      ++ a list of points; the default parameters \spad{1/2} for the
      ++ fraction and \spad{5/1} for the scale are used in the
      ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
      ++ function.
    clip: L L Pt -> CLIPPED
      ++ clip(ll) performs two-dimensional clipping on a list of lists
      ++ of points, \spad{ll}; the default parameters \spad{1/2} for
      ++ the fraction and \spad{5/1} for the scale are used in the
      ++ \fakeAxiomFun{iClipParametric} subroutine, which is called by this
      ++ function.

++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package provides for square-free decomposition of
++ univariate polynomials over arbitrary rings, i.e.
++ a partial factorization such that each factor is a product
++ of irreducibles with multiplicity one and the factors are
++ pairwise relatively prime. If the ring
++ has characteristic zero, the result is guaranteed to satisfy
++ this condition. If the ring is an infinite ring of
++ finite characteristic, then it may not be possible to decide when
++ polynomials contain factors which are pth powers. In this
++ case, the flag associated with that polynomial is set to "nil"
++ (meaning that that polynomials are not guaranteed to be square-free).

UnivariatePolynomialSquareFree(RC:IntegralDomain,P):C == T

22.17.1 UserDefinedVariableOrdering (UDVO)

Exports:
resetVariableOrder getVariableOrder setVariableOrder

— package UDVO UserDefinedVariableOrdering —

```
)abbrev package UDVO UserDefinedVariableOrdering
++ Author: Manuel Bronstein
++ Date Created: March 1990
++ Date Last Updated: 9 April 1991
++ Description:
++ This packages provides functions to allow the user to select the ordering
++ on the variables and operators for displaying polynomials,
++ fractions and expressions. The ordering affects the display
++ only and not the computations.

UserDefinedVariableOrdering(): with
  setVariableOrder  : List Symbol -> Void
    ++ setVariableOrder([a1,...,an]) defines an ordering on the
    ++ variables given by \spad{a1 > a2 > ... > an > other variables}.
  setVariableOrder  : (List Symbol, List Symbol) -> Void
    ++ setVariableOrder([b1,...,bm], [a1,...,an]) defines an ordering
    ++ on the variables given by
    ++ \spad{b1 > b2 > ... > bm >} other variables \spad{>  a1 > a2 > ... > an}.
  getVariableOrder  : () -> Record(high:List Symbol, low:List Symbol)
    ++ getVariableOrder() returns \spad{[[b1,...,bm], [a1,...,an]]} such that
    ++ the ordering on the variables was given by
    ++ \spad{setVariableOrder([b1,...,bm], [a1,...,an])}.
  resetVariableOrder: () -> Void
    ++ resetVariableOrder() cancels any previous use of
    ++ setVariableOrder and returns to the default system ordering.
 == add
  import UserDefinedPartialOrdering(Symbol)

Chapter 23

Chapter V

23.1 package VECTOR2 VectorFunctions2

23.1.1 VectorFunctions2 (VECTOR2)

Exports:
map reduce scan

— package VECTOR2 VectorFunctions2 —

```
)abbrev package VECTOR2 VectorFunctions2
++ Author:
++ Date Created:
++ Date Last Updated:
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
```

```
++ References:
++ Description:
++ This package provides operations which all take as arguments
++ vectors of elements of some type \spad{A} and functions from \spad{A} to
++ another of type B. The operations all iterate over their vector argument
++ and either return a value of type B or a vector over B.

VectorFunctions2(A, B): Exports == Implementation where
  A, B: Type

  VA ==> Vector A
  VB ==> Vector B
  O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)
  UB ==> Union(B,"failed")

  Exports ==> with
    scan   : ((A, B) -> B, VA, B) -> VB
      ++ scan(func,vec,ident) creates a new vector whose elements are
      ++ the result of applying reduce to the binary function func,
      ++ increasing initial subsequences of the vector vec,
      ++ and the element ident.
    reduce : ((A, B) -> B, VA, B) -> B
      ++ reduce(func,vec,ident) combines the elements in vec using the
      ++ binary function func. Argument ident is returned if vec is empty.
    map    : (A -> B, VA) -> VB
      ++ map(f, v) applies the function f to every element of the vector v
      ++ producing a new vector containing the values.
    map : (A -> UB, VA) -> Union(VB,"failed")
      ++ map(f, v) applies the function f to every element of the vector v
      ++ producing a new vector containing the values or \spad{"failed"}.

=====================================================================
ZeroDimensionalSolvePackage examples
=====================================================================

The ZeroDimensionalSolvePackage package constructor provides
operations for computing symbolically the complex or real roots of
zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned
roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of
irreducible regular chains.  These representations are computed by the
univariateSolve operation (by calling the
InternalRationalUnivariateRepresentationPackage package constructor
which does the job).

Real roots are given by means of tuples of coordinates lying in the
RealClosure of the coefficient ring.  They are computed by the
realSolve and positiveSolve operations.  The former computes all the
solutions of the input system with real coordinates whereas the later
concentrate on the solutions with (strictly) positive coordinates.  In
both cases, the computations are performed by the RealClosure constructor.

Both computations of complex roots and real roots rely on triangular
decompositions.  These decompositions can be computed in two different
ways.  First, by a applying the zeroSetSplit operation from the REGSET
domain constructor.  In that case, no Groebner bases are computed.
This strategy is used by default.  Secondly, by applying the zeroSetSplit
from LEXTRIPK.  To use this later strategy with the operations
univariateSolve, realSolve and positiveSolve one just needs to use an
extra boolean argument.
```

```
Note that the way of understanding triangular decompositions is
detailed in the example of the RegularTriangularSet constructor.

The ZeroDimensionalSolvePackage constructor takes three arguments.The
first one R is the coefficient ring; it must belong to the categories
OrderedRing, EuclideanDomain, CharacteristicZero and RealConstant. This
means essentially that R is Integer or Fraction(Integer).  The second
argument ls is the list of variables involved in the systems to solve.
The third one MUST BE concat(ls,s) where s is an additional symbol used
for the univariate representations. The abbreviation for
ZeroDimensionalSolvePackage is ZDSOLVE.

We illustrate now how to use the constructor ZDSOLVE by two examples:
the Arnborg and Lazard system and the L-3 system (Aubry and Moreno
Maza).  Note that the use of this package is also demonstrated in the
example of the LexTriangularPackage constructor.

Define the coefficient ring.

  R := Integer
    Integer
                        Type: Domain

Define the lists of variables:

  ls : List Symbol := [x,y,z,t]
    [x,y,z,t]
                        Type: List Symbol

and:

  ls2 : List Symbol := [x,y,z,t,new()$Symbol]
    [x,y,z,t,%A]
                        Type: List Symbol

Call the package:

  pack := ZDSOLVE(R,ls,ls2)
    ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])
                        Type: Domain

Define a polynomial system (Arnborg-Lazard)

  p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z
        2       2     2
    x y z  + (x y  + (x  + x + 1)y + x)z + x y
                        Type: Polynomial Integer

  p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z
```

```
      2 2     2 2     2
   x y z  + (x y  + (x  + x + 1)y + 1)z + x
                      Type: Polynomial Integer

  p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1
     2 2 2      2      2
    x y z  + ((x  + x)y  + x y + x + 1)z + 1
                      Type: Polynomial Integer

  lp := [p1, p2, p3]
        2       2     2
   [x y z  + (x y  + (x  + x + 1)y + x)z + x y,
      2 2     2 2     2
    x y z  + (x y  + (x  + x + 1)y + 1)z + x,
     2 2 2      2      2
    x y z  + ((x  + x)y  + x y + x + 1)z + 1]
                      Type: List Polynomial Integer
```

Note that these polynomials do not involve the variable t; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

```
  triangSolve(lp)$pack
   [
    {
         20     19      18      17       16      15       14       13       12

         - 43786426z   - 35696474z   - 58724172z   - 61480792z   - 47452440z
       +
                 9            8            7            6            5
         - 62378085z  - 55776527z  - 33940618z  - 42233406z  - 21122875z
       +
                 4            3           2
         - 22958177z  - 13504569z  + 8448317z  + 1195888z - 202934
       ,
         3       2       3    2               2              2
       ((z  - 2z)y  + (- z  - z  - 2z - 1)y - z  - z + 1)x + z  - 1}
      ]
                      Type: List RegularChain(Integer,[x,y,z,t])
```

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```
  univariateSolve(lp)$pack
   [
    [
      complexRoots =
           12      11      10     9     8      7      6      5     4     3

           Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,
                             coordinates: List Polynomial Integer)
```

We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial p(?) which defines a simple algebraic extension of the field of fractions of R. The second one consists of multivariate polynomials pol1(x,%A), pol2(y,%A) and pol3(z,%A). Each of these polynomials involve two variables: one is an indeterminate x, y or z of the input system lp and the other is %A which represents any root of p(?). Recall that this %A is the last element of the third parameter of ZDSOLVE. Thus any complex root ? of p(?) leads to a solution of the input system lp by replacing %A by this ? in pol1(x,%A), pol2(y,%A) and pol3(z,%A). Note that the polynomials pol1(x,%A), pol2(y,%A) and pol3(z,%A) have degree one w.r.t. x, y or z respectively. This is always the case for all univariate representations. Hence the operation univariateSolve replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the LexTriangularPackage package constructor.

We now compute the solutions with real coordinates:

```
  lr := realSolve(lp)$pack

      ]
    ]
                    Type: List List RealClosure Fraction Integer
```

The number of real solutions for the input system is:

```
  # lr
    8
                    Type: PositiveInteger
```

Each of these real solutions is given by a list of elements in RealClosure(R). In these 8 lists, the first element is a value of z, the second of y and the last of x. This is logical since by setting the list of variables of the package to [x,y,z,t] we mean that the elimination ordering on the variables is t < z < y < x. Note that each system treated by the ZDSOLVE package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it-self and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation takes between 30 sec. and 5 min, depending on your machine.

```
  [ [approximate(r,1/1000000) for r in point] for point in lr]

           6574997982787261696305321767320171723725209 6
       ]
     ]
                    Type: List List Fraction Integer
```

We can also concentrate on the solutions with real (strictly) positive coordinates:

```
  lpr := positiveSolve(lp)$pack
    []
                    Type: List List RealClosure Fraction Integer
```

Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

```
  f0 := x**3 + y + z + t- 1
             3
    z + y + x  + t - 1
                     Type: Polynomial Integer

  f1 := x + y**3 + z + t -1
         3
    z + y  + x + t - 1
                     Type: Polynomial Integer

  f2 := x + y + z**3 + t-1
     3
    z  + y + x + t - 1
                     Type: Polynomial Integer

  f3 := x + y + z + t**3 -1
                  3
```

```
    z + y + x + t  - 1
                    Type: Polynomial Integer

  lf := [f0, f1, f2, f3]
           3             3             3                                3
  [z + y + x  + t - 1,z + y  + x + t - 1,z  + y + x + t - 1,z + y + x + t  - 1]
                    Type: List Polynomial Integer
```

First compute a decomposition into regular chains (i.e. regular triangular sets).

```
  lts := triangSolve(lf)$pack
  [
      2           3        3
    {t  + t + 1, z  - z - t  + t,
                3      2      2      3           6     3            3      2
       (3z + 3t  - 3)y  + (3z  + (6t  - 6)z + 3t  - 6t  + 3)y + (3t  - 3)z
      +
           6     3          9     6     3

   [%B18,- - %B18  + -,- - %B18  + -,- - %B18  + -]]
          3         3   3         3   3         3
                      Type: List List RealClosure Fraction Integer
```

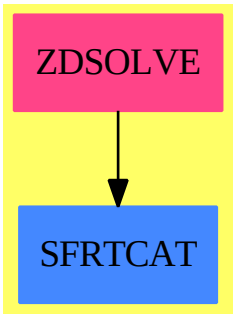
The number of real solutions for the input system is:

```
  #lr2
    27
                              Type: PositiveInteger
```

Another example of computation of real solutions illustrates the LexTriangularPackage package constructor.

We concentrate now on the solutions with real (strictly) positive coordinates:

```
  lpr2 := positiveSolve(lf)$pack
              1     3   1   1     3   1   1     3   1
     [[%B40,- - %B40  + -,- - %B40  + -,- - %B40  + -]]
              3         3   3         3   3         3
                              Type: List List RealClosure Fraction Integer
```



Finally, we approximate the coordinates of this point with 20 exact digits:

```
  [approximate(r,1/10**21)::Float for r in lpr2.1]
   [0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291,
    0.3221853546 2608559291]
                              Type: List Float
```

++ Description:
++ A package for computing symbolically the complex and real roots of
++ zero-dimensional algebraic systems over the integer or rational
++ numbers. Complex roots are given by means of univariate representations
++ of irreducible regular chains. Real roots are given by means of tuples
++ of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++ This constructor takes three arguments. The first one \spad{R} is the
++ coefficient ring. The second one \spad{ls} is the list of variables
++ involved in the systems to solve. The third one must be \spad{concat(ls,s)}
++ where \spad{s} is an additional symbol used for the univariate
++ representations.
++ WARNING. The third argument is not checked.
++ All operations are based on triangular decompositions.
++ The default is to compute these decompositions directly from the input
++ system by using the \spadtype{RegularChain} domain constructor.
++ The lexTriangular algorithm can also be used for computing these
++ decompositions (see \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations univariateSolve, realSolve and
++ positiveSolve admit an optional argument.
```

  Exports ==  with
     triangSolve: (LP,B,B) -> List RegularChain(R,ls)
       ++ \spad{triangSolve(lp,info?,lextri?)} decomposes the variety
       ++ associated with \axiom{lp} into regular chains.
       ++ Thus a point belongs to this variety iff it is a regular
       ++ zero of a regular set in in the output.
       ++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
       ++ If \axiom{lp} is not zero-dimensional then the result is only
       ++ a decomposition of its zero-set in the sense of the closure
       ++ (w.r.t. Zarisky topology).
       ++ Moreover, if \spad{info?} is \spad{true} then some information is
       ++ displayed during the computations.
       ++ See zeroSetSplit from RegularTriangularSetCategory(lp,true,info?).
       ++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm
       ++ is called
       ++ from the \spadtype{LexTriangularPackage} constructor
       ++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
```

```
    ++ Otherwise, the triangular decomposition is computed directly from
    ++ the input
    ++ system by using the zeroSetSplit from RegularChain
  triangSolve: (LP,B) -> List RegularChain(R,ls)

    ++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
  realSolve: (LP,B,B) -> List REALSOL
    ++ \spad{realSolve(ts,info?,check?)} returns the same as
    ++ \spad{realSolve(ts,info?,check?,false)}.
  realSolve: (LP,B) -> List REALSOL
    ++ \spad{realSolve(ts,info?)} returns the same as
    ++ \spad{realSolve(ts,info?,false,false)}.
  realSolve: LP -> List REALSOL
    ++ \spad{realSolve(lp)} returns the same as
    ++ \spad{realSolve(ts,false,false,false)}
  positiveSolve: RegularChain(R,ls)  -> List REALSOL
    ++ \spad{positiveSolve(ts)} returns the points of the regular
    ++ set of \spad{ts} with (real) strictly positive coordinates.
  positiveSolve: (LP,B,B) -> List REALSOL
    ++ \spad{positiveSolve(lp,info?,lextri?)} returns the set of the points
    ++ in the variety associated with \spad{lp} whose coordinates are
    ++ (real) strictly positive.
    ++ Moreover, if \spad{info?} is \spad{true} then some information is
    ++ displayed during decomposition into regular chains.
    ++ If \spad{lextri?} is \spad{true} then the lexTriangular
    ++ algorithm is called
    ++ from the \spadtype{LexTriangularPackage} constructor
    ++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
    ++ Otherwise, the triangular decomposition is computed directly
    ++ from the input
    ++ system by using the zeroSetSplit from \spadtype{RegularChain}.
    ++ WARNING. For each set of coordinates given by
    ++ \spad{positiveSolve(lp,info?,lextri?)}
    ++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
  positiveSolve: (LP,B) -> List REALSOL
    ++ \spad{positiveSolve(lp)} returns the same as
    ++ \spad{positiveSolve(lp,info?,false)}.
  positiveSolve: LP -> List REALSOL
    ++ \spad{positiveSolve(lp)} returns the same as
    ++ \spad{positiveSolve(lp,false,false)}.
  squareFree: (TS) -> List ST
    ++ \spad{squareFree(ts)} returns the square-free factorization
    ++ of \spad{ts}. Moreover, each factor is a Lazard triangular set
    ++ and the decomposition
    ++ is a Kalkbrener split of \spad{ts}, which is enough here for
    ++ the matter of solving zero-dimensional algebraic systems.
    ++ WARNING. \spad{ts} is not checked to be zero-dimensional.
